22. The exfoliation of the cuticle in pityriasis differs from that which takes place in all the varieties of *psoriasis*. For in this latter eruption the cuticle is thickened, rough, dry, and of a dull white colour; and the red patches always rise above the level of the surface, while those of pityriasis are not at all prominent. In *psoriasis*, also, the inflamed surface, even when deprived of the squamæ, remains dry, while that of pityriasis exudes a serous fluid. In the former the integuments are not swollen and painful, excepting in *psoriasis inveterata*, and in it only to a limited extent; while in the more acute or inflammatory states of the latter they are often painful and swollen over a large extent of surface. The heat and pruritus in pityriasis, also, are much more troublesome than in *psoriasis*. The same circumstances also distinguish pityriasis from the *leprous form* of *psoriasis*, with this distinction in addition, that the leprous variety generally assumes a circular form, and heals from the centre to the circumference. The detachment of the cuticle in *ichthyosis* is not preceded by redness or morbid sensation of the skin, and the desquamation following chronic *lichen* and *eczema* is preceded by papule and vesicles.

23. *III. PROGNOSIS.*—Pityriasis is one of the

most obstinate affections of the skin, more especially the more general forms of it. Even the local varieties are difficult to remove, and often return again and again, especially after errors in diet, and during disorder of the digestive organs. Of these latter varieties, that affecting the lips and mouth is the most rebellious. The duration and extent of the affection, and the association of it with internal disorder, as well as the nature of that disorder, should all be duly considered before an opinion as to the probable effect of treatment is given, and before the means of cure adopted. In all severe and complicated cases, more especially where the eruption is more or less general, and the digestive and respiratory mucous surfaces affected, the removal of the complaint is a work of time, and is not to be accomplished without effecting a change in the constitution by diet and regimen.

24. IV. CAUSES AND COMPLICATIONS.—The causes of this eruption are often obscure, and are more rarely local than constitutional, or such as affect the digestive organs, and through them the state of the constitution. Local irritants, the use of combs, or hard hair-brushes, the kind of soap used, and the operation of shaving, have been usually considered as exciting causes; but I believe that they are much less concerned in producing this affection than the following, namely, too full or rich living; improper or unwholesome diet; the frequent use of pork, bacon, and dried, smoked, or preserved meats, or of shell-fish; prolonged and repeated irritation of the gastro-intestinal surface, by these or by other articles of an indigestible kind; drinking cold fluids when perspiring; a morbid condition of the gastro-intestinal secretions; torpor of the liver, and a disordered state of the biliary and pancreatic secretions; exhausting discharges, and anxiety and exertion of mind. There can be no doubt of either or several of these causes being the most efficient in causing a return of this eruption in those who have been before attacked, and in aggravating all the symptoms in those who are already affected. The more general forms of the eruption are often associated with dyspepsia, flatulence, and chronic inflammatory action of either the pulmonary or the gastro-intestinal mucous surface, or even of both.

25. V. TREATMENT.—A. The local varieties of pityriasis generally require the utmost attention to cleanliness, and soothing and emollient applications.—a. When the *hairy scalp* is affected with the more severe forms of this eruption, the hair should be cut as short as possible, and the dried exudations and squamæ softened by means of poultices and the vapour douche, the latter of which should be continued for some time, and alternated with alkaline or emollient lotions. If there be much redness and heat of the surface with serous exudation, leeches ought to be applied behind the ears, and the calomel ointment (one drachm of calomel to one ounce of ointment) rubbed over the inflamed surface once in the twenty-four hours, after carefully washing the surface with an emollient soap, such as camphor or palm-oil soap. At the same time the bowels should be freely evacuated, the abdominal secretions and excretions duly promoted, and the cutaneous

exhalations increased by means of purgatives, alternatives, and cooling diaphoretics.

26. Due attention ought also to be paid to *diet*. The stomach ought never to be overloaded, and the quantity of animal food should be very much diminished, if it be partaken of largely, or even more than very moderately. Pork, bacon, veal, fish, particularly shell-fish; dried and smoked meats, and all other articles of food which are apt to occasion or to aggravate indigestion and gastro-intestinal irritation, ought to be avoided, and farinaceous articles of food and fresh vegetables substituted for the meat dishes which are relinquished, avoiding, however, all pickled, acid, acerb, and acrid articles whatever.

27. b. These means will generally remove the more recent cases of the eruption; but the more *chronic states* are often but partially relieved by them. I have considered that this and other cutaneous eruptions, which are attended by the exposure of a considerable portion of the inflamed surface to the action of the atmosphere, especially of the oxygenous portion of it, are aggravated by whatever tends to increase that exposure, either by removing the exudation and scales formed upon this surface, or by preventing their formation, and the protection they afford until a healthy epidermis is formed beneath them; and, therefore, instead of advising various deterging lotions, usually recommended, I have directed the surface to be covered, when the accumulated scurf and scales have been removed, with some albuminous or gummy application which may completely exclude the air from the affected part. The albuminous portion of egg, the solution of isinglass, or of gum acacia, or of tragacanth, will answer this purpose sufficiently.

28. c. In those cases which are attended with flatulence, acidity, and a predominance of the uric acid or urates in the urine, and, indeed, in most of the forms of this complaint, a sufficient quantity of magnesia and precipitated sulphur may be taken every night to procure a free evacuation of the bowels in the morning; and be continued for a considerable time, observing due precautions as to diet and regimen, and attending to cleanliness. The variety of pityriasis capitis which attacks adults, and especially the aged, and is attended with little or no inflammatory action, requires chiefly attention to cleanliness, diet, and regimen, and the removal of those symptoms of indigestion and gastro-intestinal irritation which are so frequently observed to attend this eruption. In these cases, the alkaline carbonates, taken in gently tonic infusions; the nitrate of potash, or the hydrochlorate of ammonia, in small doses, with emollients and vegetable bitters; or these with the hydrocyanic acid, will often be of service. The bowels should also be regulated by means of magnesia and sulphur, as just advised. In these cases, dyspepsia and gastro-intestinal irritation are generally associated with debility; and we shall in vain endeavour to remove the former if we neglect the latter, or to remove the eruption if we overlook these complications.

29. d. Mr. E. WILSON advises, after the inflammatory action is removed, some weakly-stimulating application to the surface, such as alkaline lotion, consisting of a drachm of liquor

potassæ to half a pint of emulsion of bitter almonds, or camphor spirit, or a weak solution of the bichlorate of mercury. A solution of two or three grains of bichloride of mercury, in half a pint of emulsion of bitter almonds, he considers best suited for patches on the face; and the zinc ointment for pityriasis palpebrarum, præputialis, and pudendalis. The vapour bath or douche, with the white precipitate ointment, are recommended by RAYER for pityriasis, palmaris, and plantaris. In these varieties, I believe that the recently-prepared calomel ointment, and due protection of the surface affected in the way just advised (§ 27), will be found preferable to the means directed by these writers.

30. *B. The more general states of pityriasis* are very frequently complicated with an inflammatory or congested state of the digestive or respiratory mucous surfaces, or with disorder of the abdominal organs; and hence the necessity of having a strict reference to these associations of disorder during the treatment.—

*a.* If the patient be young, robust, or plethoric, venesection to a moderate amount, and even the repetition of it, will be necessary, especially in recent and acute cases. Sometimes these complications appear not until the pityriasis has been of some duration; but in these blood-letting may not the less be required. Still, the circumstances of the case ought to be taken into account; for this form of the eruption occasionally appears in persons exhausted by mental exertion and anxiety; and for these relaxation and a complete change of habits and modes of living are required. Temperate mucilaginous baths, due regulation of the bowels, cooling diaphoretics, especially the liquor ammoniæ acetatis, spiritus ætheris nitrici, potassæ nitras, or the ammoniæ hydrochloras, taken in emollients or demulcents; the nitro-hydrochloric acids, taken internally, or applied externally, and a farinaceous, demulcent, and vegetable diet, are the means which deserve the greatest confidence.

31. *b.* If the bowels require assistance, the repeated use of the magnesia and sulphur, as above advised (§ 28), will be found most serviceable in this and in other forms of the eruption. If they become relaxed, ipecacuanha with any of the preparations of opium, or with the tinctura camphoræ composita, and a frequent recourse to mucilaginous baths, and to applications of albumen, or of solutions of gum, &c., over the more inflamed and denuded surfaces, will prove most beneficial. In this as well as in most other forms of the eruption, the preparations of arsenic, or even of iodine, are not so serviceable as in some other scaly affections, particularly when dyspeptic symptoms or gastro-intestinal disorders are present. But cases occasionally occur in which they are very advantageously taken immediately after a meal; and when thus administered they will not induce or aggravate these symptoms.

32. Mr. WILSON remarks that the local affection "is to be treated by emollient baths, fomentations, alkaline baths, and opium to lull the pruritus." Dr. A. T. THOMSON advises a lotion, consisting of one drachm of the solution of potash; one drachm of the dilute hydrocyanic acid, and seven ounces of the mixture of bitter almonds to be applied to the af-

fected surface, in order to quell the pruritus. I cannot quite approve of these means of cure, for the reasons already assigned (§ 27), especially of the more detergent substances employed, and am not surprised at their frequent failure. The treatment recommended by BATEMAN will be found more successful than that now noticed, namely, a combination of antimonials with decoction of woods, and warm baths. And when the irritability of the skin is not very great the application to the parts of an astringent lotion containing alum, or the di-acetate of lead, or a lotion containing borax. Emollient lotions and baths, containing also the sulphuret of potassium, are often useful. Mr. ERICSEN advises them to be aided by an ointment of white precipitate of calamine, or of the oxide of zinc.

33. *c. The Harrowgate and other sulphurous waters* are often of use in all the varieties of pityriasis. In a remarkably severe case of the general form of the eruptions in a married lady, about the period of the cessation of the menses, which was under my care, a prolonged course of these waters, following an active course of medicine, effected a complete and permanent cure. The discoloured varieties of the eruption, described by WILLAN and BATEMAN, and but rarely met with, require the same treatment as that advised above.

34. In most instances, especially the more chronic and general states of this eruption, comparatively little benefit will accrue from any method of cure, if the state of the digestive organs, and the diet and regimen of the patient, be neglected. For in this, as well as in all other chronic diseases of the skin, a complete and enduring cure can be obtained only by a change in the constitution, brought about by a suitable diet and regimen, and habits of life. What the diet, regimen, and habits ought to be cannot be stated with precision, as they should be partially accommodated to the circumstances of individual cases; but, in general, those in which the patient has indulged before and during the commencement of the affection require change. Abstemious and regular habits should be adopted, avoiding rich, indigestible, and heating articles of food, and stimulating beverages, and substituting farinaceous and vegetable substances, as far as may be prudent. Mental exertion and anxiety should also be avoided as much as possible; exercise in the open air ought to be regularly enjoyed; and sexual indulgences restrained within due bounds.\*

BIBLIOG. AND REFER.—Galen, De Composit. Medicament. secundum Locum, lib. i.—Celsus, lib. vi., 2.—Oribasius, Synopsis, lib. vi., cap. 25.—Aëtius, lib. vi., cap. 66.—Alexander Tral., lib. i., cap. 5.—Paulus Ægineta, lib. iii., cap. 3.—Avicenna, lib. iv., Fen. vii., tr. 2, cap. 24.—Forsters, lib. viii., Observ., 13.—Mercuriali, De Morbis

\* I have at present under my care a case of general pityriasis in a man, of great extent and severity. He has tried courses of the solution of the iodide of mercury and arsenic, of the sulphur and vapour baths, and the Harrowgate and Leamington waters, without benefit. He is about fifty years of age, has lost an arm, is of a full habit of body, and has lived freely. A severe diet, chiefly of farinaceous and vegetable food, sponging the surface with cooling lotions, exercise in the open air, and a course of alterative medicines were prescribed for him, but as yet the benefit derived is only partial, the restricted diet and prescribed regimen not having been observed. The great difficulty in the treatment of this and other diseases of the skin, is to convince patients of the necessity of observing a strict regimen, or rather to secure their faithful and continued adoption of the diet and regimen prescribed.

Medical literature furnishes little either truly satisfactory or practically useful respecting the pathology, the constitutional relations, the complications, and the treatment of this obstinate and generally symptomatic eruption.

PLAGUE. See PESTILENCE, SEPTIC OR GLANDULAR.

PLETHORA. See BLOOD, EXUBERANCE OF.

PLEURA, DISEASES OF.—*SYNON.* Πλευρά vel πλευρον, pleura, the membrane covering the internal surface of the ribs, according to the ancient meaning; now the membrane covering the internal parietes of the thorax, and reflected over both lungs.—*Pleurc*, Fr. *Brustfell*, *rippenfell*, Germ.

1. I shall consider at this place those diseases which commence and are seated chiefly in this membrane; but the consecutive changes to which the pleura is liable will also receive due attention. *Inflammations of the pleura* will be first discussed, and next the other organic lesions, which either commence in, or consecutively implicate this membrane, will be treated of, occasional reference being made to associated affections and diseases of the LUNGS (see that article) and of other connected and adjoining organs.

INFLAMMATION OF THE PLEURA.—*SYNON.* Pleuritis, πλευριτις, πλευριτις νοσος, morbus lateralis, the side disease. Morbus pleuriticus, Celsus. Passio pleuritica, Morbus costalis, Pleuresis, Auct. Var. Febris Pleuritica, Hoffmann. Pleuritis Pulmonis, Pleuroperipneumonia, Auct. Pleuritis, Vogel, Sagar, Boerhaave, &c. Pneumonia pleuritica, Cullen. Cauma pleuritica, Young. Empresma pleuritica, Good. Inflammatio pleura; Pleurisie, French. Brustfellentzündung, Scitenstich, Germ. Pleurite, plurisia, Ital. Plurisy.

CLASSIF.—I. Class, 2d Order (Cullen). II. Class, 3d Order (Good). III. CLASS, I. ORDER (Author in Preface).

2. DEFIN.—i. NOSOLOG.—*Acute pain in the chest, aggravated by inspiration, commencing with chills or rigours, followed by increased heat, a hard and accelerated pulse; short, dry cough; and by difficult, short, or disordered respiration.*

ii. PATHOLOG. DEFIN.—*Inflammation, commencing in or implicating one or more parts of the pleural expansions, attended either by more or less of a consistent albuminous exudation, false membrane or adhesion, and by a fluid effusion, varying in their characters with the varying states of different cases; causing pain, symptomatic fever, disordered respiration, dulness on percussion, and alteration of the respiratory sounds.*

3. Pleurisy has been mentioned by *Hippocrates* and *Celsus* in several places, and more

distinctly by *Galen*; but *Aretæus* was the first to describe it with precision, and with reference to the treatment. *Cælius Aurelianus*, *Alexander Trallianus*, and *Paulus Ægineta* have also treated of it at considerable length. All these writers have viewed the disease as seated in the pleura lining the ribs, or external parietes of the chest. Modern physicians, who agreed with ancients in limiting the malady to the pleura, did not also agree with them in believing that it was confined to this portion of the pleural surface, but that it was seated, with, probably, much greater frequency, in the pleura reflected over the lungs and other parts. While *Boerhaave*, his commentator *Van Swieten*, and others contended for the separate and distinct affection of the pleura, *Sydenham*, *Hoffmann*, *Triller*, and *Morgagni* believed that the pleura and the substance of the lungs were generally both implicated, and that the one could rarely or never be inflamed without the other being also attacked. Hence *pleuro-pneumonia*, or *pleuro-pneumony*, was used to designate inflammation of these distinct structures. This latter view was followed by *Cullen*, *Portal*, the *Franks*, and many others. Nevertheless, it is now fully demonstrated by *post-mortem* examinations, as well as by the physical and rational symptoms during life, that inflammation may commence in, and be limited to, the pleura in some cases, and may be equally confined to the substance of the lungs in others; although in perhaps a still more numerous class of cases, it may originate in the one and extend to the other, implicating either of them more or less, as I have fully shown when treating of *inflammations of the lungs* (see art. LUNGS, § 73-75), and as the researches of *Laennec*, *Andral*, *Louis*, *Cruveilhier*, *Williams*, *Forbes*, *Chomel*, and *Stokes* also have fully demonstrated.

4. It has been fully shown by *Dr. Stokes* that the superficial description of many anatomical writers has given rise to incorrect views as to the connexion between the pleura and the parts over which the pleura is reflected. Instead of this membrane being connected to these parts simply by means of a subjacent cellular tissue, it has interposed, between it and these parts, a thin but dense fibrous membrane, which entirely envelopes the lungs, and forms a strong capsule for these organs. *Dr. Stokes* remarks, that this capsule, in the healthy state, though possessing great strength, is transparent, a circumstance in which it differs from the fibrous capsule of the pericardium, and which has probably caused its being heretofore overlooked; and that it is always more perceptible in disease implicating the pleura and subjacent tissues when they are more or less hypertrophied and rendered opaque. "This fibrous tunic invests the whole of both lungs, covers a portion of the great vessels, and the pericardium seems to be but its continuation, endowed in that particular situation with a still greater degree of strength, for purposes sufficiently obvious. It covers the diaphragm, where it is more opaque, and, in connexion with the pleura, lines the ribs, and, turning, forms the mediastina, which thus are shown to consist of four layers, two serous and two fibrous." (P. 460.) This conformation of the investments of the lungs and adjoining parts is interesting in a

physiological and pathological as well as an anatomical point of view. It establishes an additional analogy between the lungs and the parenchymatous and glandular organs of the abdomen, which have their fibrous capsules; and illustrates the general law of the constant association of serous and fibrous membranes, as we see in the arachnoid, pericardium, peritoneum, tunica vaginalis testis, and the synovial capsules. Considered pathologically, Dr. Stokes adds, it may explain the pain of pleuritis and pleurodynia, and the rarity of perforations of the pleura, so remarkable when considered in connexion with the frequency of ulcerations of the lung, which constantly approach so close to the surface as to be bounded by the fibro-serous membrane alone. "In pleuritis, with effusion, its existence may assist in explaining the binding down of the lung, and its corrugated appearance after the removal of the effusion." It may also be the seat of ossifications of the pleura; indeed, there can be little doubt of this being the case.

5. Notwithstanding this structure of the thoracic linings, we find that the cavities are capable of considerable dilatation, and that the mediastinum yields much more than is generally supposed, before the pressure of intra-thoracic accumulations. Hence, in empyema, or in pneumo-thorax of the left side, displacement of the heart, as Dr. Stokes has shown, occurs long before the intercostal spaces are obliterated, or even the diaphragm depressed. It is not improbable, however, that the strength of this fibrous tissue varies in different persons; indeed, with respect to the pericardium, the greatest difference of strength exists, for in some subjects it is dense and opaque, while in others it is nearly transparent.

6. *The varieties or states of pleuritis* are numerous; and they have been variously denominated and arranged, according to the views of those who have described them, and to the various morbid relations they furnish.—(a) Considered with respect to the character of its progress and duration, pleurisy may be either *acute* or *chronic*; and (b), both the one and the other may also be either *attended by pain* or *without pain*—may be *open* or *latent*.—(c) In relation to its extent, pleurisy may be *partial*, or circumscribed to a portion only of the pleura of one side, or much more extended on one side, but still *single*, or it may exist on both sides, or be *double*.—(d) As regards the characters of the pathological changes attending it, pleurisy may be *dry*, *adhesive*, or *pseudo-membranous*, or it may be *effusive*, *serous*, *sero-puriform*, or *purulent*.—(e) In relation to the causes and circumstances of its occurrence, pleurisy may be *primary* or *consecutive*, or it may be *spontaneous* or *traumatic*. (f) In respect of antecedent disease, it may be consequent either upon other diseases of the chest, or upon constitutional maladies, more especially the eruptive fevers.—(g) Pleuritis may, moreover, be *simple* or *complicated*; and it may be *simple* from the commencement and continue so, or it may become complicated in its course, and it may be *complicated* from the beginning, or it may be consequent upon the malady associated with it; thus it may be associated with *catarrh*, *pneumonia*, *bronchitis*, *tubercles*, *pericarditis*, *diaphragmitis*, *hepatitis*, *rheumatism*, &c.—(h) Pleurisy may be even charac-

terized according to the *states of the system* and the *diathesis*, and the circumstances in which it occurs: thus it may be *sthenic*, or *asthenic*, or *bilious*, or *typhoid*, or *malignant*, or *cachectic*, or *puerperal*.—(i) It may, lastly, be *true* or *false*.

7. Having premised these remarks, I shall first notice the *causes of pleurisy*, and afterward describe the principal *forms and states* which this disease assumes, with their *terminations*, their *diagnosis*, and the *appearances on dissection*, concluding with the *treatment* which appears most appropriate to each of these states.

8. I. THE GENERAL CAUSES OF PLEURISY.—Pleurisy occurs in all *ages* and in both *sexes*—in infancy and childhood as well as in adult age; and in this latter somewhat more frequently than in old age. It is much more frequent in males than females, probably in the proportion of five to three, and owing to the greater exposure of the former to the exciting causes. It is most prevalent among persons much exposed to the vicissitudes of season and weather, and those actively engaged in outdoor occupations, more particularly such as require physical exertion. It is met with somewhat oftener in those of a sanguine temperament, and robust or plethoric habit of body, than in others; but this may admit of some doubt. It occurs more frequently in winter and spring than in the other seasons, and in this it accords with pneumonia, both these maladies occasionally becoming so prevalent in those two seasons as to be almost epidemic. Nevertheless, pleurisy may be more than usually prevalent, also, during summer and autumn, as it manifestly was during the spring and summer of 1846, during which seasons, however, there seemed to be a tendency to inflammatory affections of serous membranes, and these often of an asthenic character.

9. A. *The various circumstances which predispose pleurisy* are not determined with precision. There can be no doubt, however, that previous disease of the respiratory passages or substance of the lungs, or the actual presence of these and eruptive fevers, are the most frequent and influential. To these may be added the arrest of accustomed discharges, and the suppression of cutaneous eruptions and of painful affections, before the constitutional derangement of which they are the external manifestations is removed, for there are often predisposing causes, although they may not actually excite or determine this malady, other causes commonly following upon these, and determining the morbid action to the pleura or other serous membranes.

10. B. The most influential *exciting causes* are certainly exposure to cold in the numerous modes of its application, &c., and external injury.—a. The vicissitudes of season, of temperature, and of other atmospheric conditions, have a marked influence on the prevalence of this disease. It is generally supposed that cold and dry states of the air occasion pleurisies more frequently than cold and humid states. This is probably the case, but it is not demonstrated, nor is it easily demonstrable, as there are generally numerous other circumstances which should be taken into the account. There can be no doubt, however, that cold applied to the surface of the chest, or the cold generated by currents of air passing over this part of the

body, or even over other parts, and damp or wet clothes upon either the trunk or the extremities, more especially when the surface has been perspiring at the time, or shortly before, are frequent causes of pleurisy.

11. *b. Injuries or other mechanical causes* are frequent and sufficiently manifest, especially fractures of the ribs, penetrating wounds of the thorax, and contusions. I believe that the influence of the last of these has often been underrated, and that contusions and superficial injury even of a slight kind have occasioned pleurisy more frequently than has generally been supposed. In some states of the constitution, by no means recognizable previously, superficial and painful injuries, such as severe burns, scalds, and lacerations of the surface, are followed by inflammation of the pleura; and in some instances the injury may have been so severe as to have its effects propagated to the intercostal muscles, and thence to the costal pleura; but, in other instances, this explanation can hardly be entertained, although the frequency of pleurisy subsequently to such injuries fully justifies a belief in the sequence being that of cause and effect, while nervous communications, connexions, and influence sufficiently account for the phenomenon.

12. *c. The pathological causes, or antecedent diseases*, require some notice in relation to the occurrence of pleurisy, more especially as the most frequent appearances of this malady are of this description. The common supervention of pleurisy upon general and lobular pneumonia, upon tubercles in the lungs, the rupture of a tubercular cavity, or tubercular perforation of the lung, and upon other organic lesions of this organ, is well known. But it is not always sufficiently recollected, at least it has not been sufficiently noticed by authors, that pleurisy is often consequent upon inflammations of the liver, of the diaphragm, and of the pericardium, and still more frequently upon rheumatism. Pleurisy may either follow or coexist with these, and more frequently with inflammation of the liver and diaphragm than is generally supposed. It may also follow partial or general peritonitis, and become the most dangerous part of the complicated malady. It is well known that diseases of the mamma, more especially the malignant maladies of this organ, often extend to the pleura, and occasion one of the worst forms of pleuritis; and pleurisy, generally with effusion, is one of the most unfavourable consequences, and not the least unfrequent, of inflammations of the veins and of the lymphatics, of punctures or the inoculation of morbid fluids during dissections, and of organic diseases of the kidneys.

13. *Eruptive fevers* are among the most frequent pathological causes of pleurisy, this disease commencing either during the acme of the eruptive fever, or during the subsidence of the eruption, or even during the period of convalescence. When the pleurisy appears during the acme of eruptive fevers, it may be manifest, or be marked by the other phenomena, or be latent, and be detected only after death; and it may be similarly circumstanced when occurring at any period after the decline of the eruption. In the first instance, the concomitant pleurisy is to be imputed to the morbid poison in the circulating fluids that has affected the

pleura in addition to the external surface, and, indeed, other surfaces of the body. In the later appearances of pleurisy in connexion with, or subsequent to, an eruptive fever, it may be inferred that the morbid condition of the circulating fluids had not been removed by the changes which had taken place on the cutaneous surface, and by the other emunctories, but that it was still sufficient to implicate the pleura, especially if exposure of the surface, in its existing state of susceptibility, favoured determination of the circulation to internal parts. Moreover, the cutaneous function is often not restored for some time after eruptive fevers; hence the blood retains much uneliminated materials, which act injuriously upon serous exhalant surfaces, and often inflame them; and this evil and its consequences are always developed or aggravated by exposures to cold, even of the most evanescent and slightest kind, during the early periods of convalescence from these fevers. Besides, the sympathies existing between the skin and serous membranes, already insisted upon (§ 11), are also to be taken into the account when speculating on the connexions of inflammations of these surfaces.

14. The *puerperal state*, more especially the first month after delivery, is not an unfrequent cause of pleurisy; inflammation of the pleura occurring then either in a simple form, or associated with peritonitis, or with pneumonia, or with phlebitis, &c. In this particular state there can be no doubt of the disease being caused, in great measure, by the condition of the blood consequent upon the absorption of morbid matters from the uterus, and even in part from the digestive canal, aided probably, in some cases, by suppression or interruption of the eliminating or depurating functions of the skin, kidneys, and intestinal canal. In many instances, also, of puerperal fever, more especially of the adynamic and malignant states of that disease, pleuritis appears both as a complication or prominent local lesion, and as a consecutive malady; and thus pleurisy, appearing after parturition, may be viewed as resulting from analogous changes to those which occasion it in connexion with eruptive fevers, erysipelas, and some other diseases of the skin, namely, from the states of the circulating fluids, aided by interruption or suppression of the actions of the skin and other emunctories.

15. II. DESCRIPTION OF PLEURISY.—i. THE STRUCTURAL CHANGES CONSTITUTING PLEURISY.—It will be advantageous briefly to notice those changes in the pleura constituting this disease, in the earlier stages, and which exist in all cases in a greater or less degree, however early treatment may arrest their progress. These changes are identical with those characterizing inflammations of the *peritoneum*, and hence it will be unnecessary to do more than to notice them briefly. It is probable that, at the very commencement of the inflammation, there is a diminution of the serous exhalation that usually moistens or lubricates the pleura in the healthy state. This being the case, the friction between the opposing surfaces would be increased; but this condition would soon be followed by an exudation of lymph, or of an albuminous serum, which would assume various forms with the intensity and continuance of that inflammation, and the habit of body and

vital powers of the patient. The pleura, more especially in its subjacent or more fibrous layer, and the connecting cellular tissues, becomes more vascular, more opaque, and somewhat thickened, at least subsequently, and the lymph effused more copious. The liquid or lymph poured out consists of serum—an augmentation of the serous exhalation—and of a material of nutrition, the albuminous, the coagulable, or albumino-fibrinous portion. If the inflammation continue, even for a short time, the exudation of these materials, in variable proportions in different cases, proceeds rapidly, and gives rise to changes depending much upon the proportion of the latter material contained in the serous fluid. In its smallest proportion, the coagulable material is held in solution by the effused fluid; and, when withdrawn from the body, it gelatinizes upon cooling, the liquid mass assuming a jelly-like appearance. When the coagulable portion is more abundant, it forms films or coats of lymph upon the surface of the membrane; and this deposition is generally the more considerable, and the more disposed to speedy organization, the more acute the inflammation, the more plethoric and robust the patient. This coagulated lymph thus forms the false membranes, and the substance of the adhesions so frequently formed between the surfaces of the inflamed pleura. But the false membranes may exist with or without adhesions, the existence of adhesions depending much upon the quantity of the fluid effusion between the pleural surfaces. This effusion, especially when considerable, will generally gravitate to the most depending portions of the pleural cavity; and there, especially, it will tend to keep the pleuræ separate. But if the upper portions of the pleura be inflamed, they will more readily adhere, unless the fluid be very abundant. If the pleuræ be inflamed only in their lower expansions, a small quantity of fluid will be sufficient to keep them apart. When the lymph effused on the inflamed surfaces becomes organized it forms a false membrane; and if the lymph cover opposite surfaces, adhesions, through the medium of these membranes, often become firm or permanent. When the liquid effusion is small, or even considerable, various adhesions may be formed, and vary in number, appearances, and extent, in connexion with the effusion; or partial adhesions, coexisting with false membrane, may exist without any, or with very slight, effusion. In more prolonged cases, and in various other circumstances, which will appear in the sequel, various consecutive changes are observed in the pleura, and in the matters effused in its cavity; but these will be more fully noticed hereafter.

16. ii. THE SYMPTOMS AND SIGNS OF PLEURISY.—A. OF SIMPLE ACUTE PLEURISY—OR STHENIC ACUTE PLEURISY.—This, as well as other inflammations, generally commences with chills or rigours, the continuance and severity of which are generally in proportion to the severity of the attack. The rigours are either preceded, or accompanied, or followed—for no precise order of procession of their symptoms is observed—by pain or stitch in the side, aggravated by inspiration and cough. To the rigours succeed heat of surface and the usual phenomena of sympathetic inflammatory fever,

which vary with the constitution, idiosyncrasy, and vital power of the patient. The respiration is short, frequent, sometimes nearly forty in a minute, superficial, and anxious. Inspiration is interrupted, or, as it were, cut short by the lancinating pain. Cough is dry and suppressed. The chest, on percussion, furnishes a dull sound on the affected side; and, at the same time, there are diminished motion and sound of respiration, with other morbid signs, on that side. The accompanying fever is attended by nocturnal exacerbations, with more or less manifest remissions. From the fifth to the ninth day the fever subsides, either with or without critical changes. The pain of the side abates, and with it the feeling of oppression or tightness, and expectoration and respiration become more easy. Still the local changes, evinced by percussion and auscultation, remain, and often continue for a considerable period; and even, to a certain extent, during life. But more commonly they gradually disappear, and the patient recovers health and strength. Dulness on percussion is the sign which is the last observed, the breath-sound returning often long before the dulness entirely disappears. These phenomena result from the several products of inflammation collected in the cavity of the pleura, that are generally removed during the period of convalescence. This view of the symptoms of pleurisy requires, however, a more particular examination, in respect both of the diagnosis and of the treatment.

17. a. The pain or stitch in the side, characteristic of this state of the disease, indicates a more or less developed period of it. This pain is sharp or lancinating, often severe, recurs at each inspiration, and prevents the dilatation of the thorax, thus confining inspiration within certain limits. Its seat is most frequently under the nipple, at the margins of the lateral attachment of the diaphragm. It has been asked, to what is this pain owing? M. CRUVEILHIER answers this question by referring it to the friction of the costal pleura over the pulmonary pleura, which he believes to be greatest at this situation. But I doubt the existence of much friction between these surfaces, and believe that the pain is to be imputed chiefly to the stretching of the inflamed fibrous layer of the membrane during inspiration, and to the development of its morbid sensibility by this act. The pain may be felt in other situations besides that now mentioned. It may exist at any part of the affected side of the chest. It may even extend to the lumbar region, or to the lower margins of the ribs and down to the crest of the ilium; and it may exist in the mammary and sub-sternal regions, and rise as high as the margins of the third or second rib, extending even to the shoulder. The pain varies as to intensity and duration: it may be permanent or temporary, remittent or intermittent. It may be so intense as to threaten suffocation or asphyxia, either from attempting to move, or owing to the inability to dilate the chest. This, however, is most remarkable in extreme cases, and in those of *double pleurisy* (§ 61). In other instances the pain is comparatively slight, and is felt chiefly during a full inspiration, or upon coughing or sneezing, &c. In some cases the pain extends over nearly the whole of the side, and is increased upon pressure, especially on the

intercostal spaces, upon percussion, &c. I have seen, also, the pressure of the stethoscope endured with difficulty, and a certain degree of puffiness or œdema of the side or of the external parietes. In a case of pleurisy consequent upon hepatitis, very recently under my care, this external œdema and tenderness were very remarkable. I have imputed these phenomena to inflammation of the costal pleura, and to the external propagation of several of the local changes, especially excited vascular action, increased sensibility, and serous infiltration to the sub-cutaneous cellular tissue. Moreover, the pain may be entirely absent, or may exist in a situation which may not suggest the existence of pleurisy; and hence the disease has been called *latent pleurisy*, which will be considered hereafter (§ 49.)

18. *b. Respiration* is short, interrupted, superficial, and very frequent. It may even reach fifty in a minute. The frequency of respiration is generally in proportion to the severity of the pain, which checks the dilatations of the chest, and creates a necessity for an increased frequency of the act. In these cases a sudden attack of cough or sneezing almost threatens asphyxia; but I cannot agree with M. CRUVEILHIER, that asphyxia ever occurs under these circumstances, unless in double pleurisy, when much effusion has taken place. Great frequency of respiration may, however, exist independently of pain; but in this case there is generally considerable effusion. Hence this state of respiration, although no pain is complained of, should always induce a suspicion of the existence of pleurisy. When the remarkable acceleration of breathing is caused by the effusion, then attacks of cough, sneezing, &c., may be followed by fatal asphyxia, but this issue more frequently supervenes without either of these contingent causes having occasioned it.

19. *c. Cough* most frequently attends pleurisy; but it is short, dry, and suppressed, owing to the pain it causes. It sometimes, however, brings up some bronchial or tracheal mucus, and when pleurisy is complicated with catarrh, then the cough is much more severe and distressing, and often attended by a copious expectoration of the sero-mucous fluid of catarrh. Occasionally the catarrhal symptoms are not developed until the acute stage of pleurisy is subsiding, and when a free, abundant, and copious expectoration then takes place, it may be viewed as being critical; but when the sputum is viscous, adheres closely to the vessel, is rusty or streaked with blood, it may then be considered an indication of the extension of the inflammation to the substance of the lungs, and to the minute bronchi.

20. *d. Immobility of the thorax* on the affected side has been considered characteristic of pleurisy; but this is the case only to a certain extent, and is not to be depended upon, for in many severe cases it is difficult to see much difference in the degree of motion of both sides, or of different parts of the same side. Besides, immobility is often caused by pain, which may exist in the side independently of inflammation, as will appear hereafter.

21. *e. Decubitus* is most frequently on the back during the acute stage of pleurisy; sometimes it is upon the sound side, and rarely on

the affected side as long as pain is considerable; but when effusion has taken place, and the acute stage has passed away, the patient can lie only on the back or on the side in which the effusion exists. Indeed, in all chronic cases of pleurisy, or whenever effusion into the pleural cavity is great, the lung on the sound side only remains capable of performing the respiratory functions, and it necessarily requires to be unembarrassed during the discharge of these functions, either by position or any other circumstance.

22. *f. The fever* attending pleurisy may precede, for two or three days, the local symptoms, or accompany them. It generally subsides, before these symptoms disappear, for a longer or shorter period. The heat of surface varies considerably, but generally it is co-ordinate with the strength and hardness of the pulse, and is increased towards evening or night. The fever is seldom perfectly continued; it is generally slightly remittent; sometimes more manifestly so. It is much less frequently intermittent, although the latent form of the disease often presents complete morning or daily intermissions. The pulse is hard, concentrated, or constricted, and more or less accelerated, while in pneumonia it is full and developed. Hardness of the pulse was considered by BAGLIVI as the most distinctive symptom of pleurisy. The concentration and hardness of the pulse are generally remarkable in proportion to the acuteness of the pain. When effusion takes place, or is considerable, especially about the third or fourth day, or later, the febrile symptoms subside, or remit more decidedly, and sometimes the pulse intermits. These phenomena may be referred to the influence produced by the effusion upon the functions of the lungs and heart, and consequently upon the blood itself. The least mental or physical agitation, however, occasions great acceleration of the pulse in these cases, and a febrile exacerbation returns at night.

23. Although the sharp pain in the side, catching and restraining every inspiration, and rendering deep breathing or coughing almost intolerable; the short breath, and short dry cough thereby caused; the hard and quick pulse, heat of skin, &c., are often characteristic of pleurisy; yet acute inflammation, and its most important consequence, copious effusion, may have existed for many days in the pleura, without this array of symptoms. Even effusion may have taken place to a very great amount without either disturbing the respiration very sensibly, or even rousing the sensibility of the parts, if it have proceeded gradually or slowly. On the other hand, the *physical signs* are more to be depended upon than those symptoms which have been now considered. And, although they do not indicate the intensity of the inflammation, they seldom fail in announcing the presence, and most serious consequences of it. I shall therefore analyze these signs in the order in which they commonly appear.

24. *B. Physical Signs of Pleurisy.*—*a. Diminished motion* is usually observed as already stated, and is at first to be imputed to the pain; but, as pain may exist independently of inflammation, this sign cannot be depended on. The sound of respiration is also diminished in pro-

portion as the movements are restrained in the parts affected with pain.

25. *b. A sound of friction*, or a creaking sound, is sometimes heard during the movements of the chest. This is ascribed by Dr. STOKES, M. REYNAUD, and others to a defective lubrication of the opposite pleural surfaces during the early or incipient stage of inflammation—to a *dry pleurisy*. Dr. WILLIAMS ascribes this sound to the presence of lymph, and believes that its production is favoured by the lung being partially distended or pushed against the walls of the chest during respiration. It is most apt to occur where the lung is confined by adhesions or false membrane, or partially distended by tuberculous or other deposits. This sound is commonly heard about the middle parts of the chest. It generally ceases as soon as effusion into the pleural cavity is announced by percussion; but in the dry pleurisy it may continue for a long time. Dr. WILLIAMS remarks that, in three cases in which the sound was heard a few days before death, the pleura were thinly coated with a few small patches of soft granular lymph; and that, on gently rubbing the lung upon the costal pleura, a friction-sound was produced by the patches, but by no other part of the pleura. The pleural inflammation and effusion were very slight in these cases.

26. *c. Dulness on percussion*, at the most dependent parts of the affected side, is present when effusion has taken place; but there may also be some dulness on percussion of other parts, or where a considerable effusion of lymph, or false membrane, is interposed between the opposite surfaces. The effused fluid collects in the lowest part of the cavity, floating, to some extent, the lung upon it; and hence the dulness in that part. As, however, the vesicular and peripheral parts of the lung yield more readily to pressure than the tubular or more internal parts, the fluid mounts up, as it accumulates between the lung and ribs, and occasions more or less dulness, which is then distinctly heard if the percussion be gentle and abrupt. But in all cases the sound should be compared with that emitted by corresponding parts on the sound side.

27. *d. Diminished sound of respiration*, with diminution of the extent of the motions of respiration, necessarily result from the accumulation of fluid in the pleural cavity. The breath-sound is more and more weakened and shortened as effusion proceeds, and is ultimately abolished in most parts, excepting those about to be noticed. This sign, as well as that preceding and those following it, may be modified, or rendered less distinct, by adhesions previously existing between the pulmonary and costal pleura.

28. *e. Ægophony*, or the modification of the vocal resonance so denominated, occurs when the dulness on percussion and diminution of the respiratory sound reach the middle regions of the chest. The vocal resonance is heard more distinctly than usual in those regions, "and it is superficial, as if produced in the spot, separately from the oral voice; and it is changed to a small bleating, trembling note, which so much resembles the voice of a goat, that LAENNEC termed it ægophony. This modification of the voice is heard most distinctly

between the third and sixth ribs, which corresponds with the situation of the middle-sized bronchial tubes; about the spine it is generally mixed with more of a common bronchophony from the larger tubes at the root of the lung." The liquid interposed between the lung and the parietes of the chest renders the voice more audible in the above situation, by condensing the tissue of the lung, and thereby making it a better conductor of sound. The layer of fluid thus interposed, being thrown into vibration by the sound propagated from the bronchial tubes, transmits the voice to the ear of a tremulous and wiry character, or imparts to the voice, heard upon auscultation in this situation, this particular character. The high or sharp tones of the voice are best transmitted in this way. Hence ægophony is most evident in boys, women, and children with high voices. In persons with a bass voice it is more commonly limited to the inferior angle of the scapula, or near the spine; and it then approaches nearer to bronchophony from its being seated in larger tubes.

29. As the liquid increases, the ægophony becomes weaker, more distant, and loses much of its tremour, the sound much resembling a small, deep-seated voice, or a silvery echo of the original. This is owing to the amount of effused fluid, and to the compression of the lungs and tubes; and when these are much increased, the sound ceases altogether. It has not been ascertained what quantity of effusion is sufficient to produce this last effect. Dr. WILLIAMS thinks that much sound of the voice is not transmitted when the layer of serum exceeds an inch in thickness. If the ægophony continue stationary for several days, it may be inferred that the effusion is moderate, and increases very slowly, which is a favourable sign. But it is often very transient; and cases often do not come under treatment until the pleuritic effusion has become too great to give rise to ægophony. Former and existing adhesions, however, modify this as well as the other physical signs. When ægophony is most distinct it is often accompanied with bronchial respiration, especially between the scapulæ, where, also, there is a good deal of common bronchophony with it. Indeed, ægophony is merely the bronchial voice modified by transmission through a layer of fluid; and hence it may be changed into bronchophony by causing the patient to change his position so as to allow the fluid to gravitate to a different part of the cavity. Hence, also, ægophony and bronchophony often present mixed and doubtful states, which do not admit of easy distinction, although they differ sufficiently when their respective characters are well marked. The former may be stated to be a *tremulousness* of the voice when it is superficial, and an echo-like smallness when it is deep-seated; while the latter may present several other varieties.

30. *f. The diffused vibration of the voice*, which is usually felt by the hand applied to the chest, is generally intercepted and prevented by effusion into the pleural cavity. M. REYNAUD first pointed out this sign, and showed that the vibration caused by the voice pervading the common tissue of the lung, and transmitted to the parietes of the chest, is muffled and destroyed by a layer of fluid interposed between the lung

and the parietes, although ægophony may be heard at the same spot, the vibrations of the latter being too fine to be felt by the hand. When dulness on percussion is caused by solidification of a portion of the lung, the vocal vibrations are transmitted with unusual force from the tubes to the walls of the chest, and hence the opposite effect occasioned by the fluid interposed becomes an important diagnostic sign, in regard of these lesions. Partial adhesions, however, of the lungs to the costal pleura may very materially interfere with these phenomena; for there may be even more vibrations than usual felt at the adhering parts, or where the lung is pressed close to the walls of the chest; and, on the other hand, there may be solidification of the lung, and fluid or other obstruction in the bronchi may prevent the fremitus of the voice from being transmitted through them; or more or less fluid may be interposed between the solidified lung and the walls of the chest.

31. *g. Ægophony and all sounds of the voice cease* throughout the affected side as the liquid effusion increases, excepting within two or three inches of the spine; or where the lung may adhere to the walls, which frequently happens at the upper parts of the chest. The sound of respiration is not heard in all the parts of the affected side, except the interscapular region and under the clavicle; but it is much weaker in these parts.

32. *h. Enlargement and immobility of the affected side* may always be detected when the effusion is considerable. This side is first seen to be larger than the other at the end of expiration, it not diminishing equally with the sound side, especially at its lower region. The difference between the sides may be rendered more evident by encircling the chest by a piece of tape, and by fixing it at the spine and sternum; when the tape will slacken and tighten with expiration and inspiration, more evidently on the sound than on the diseased side, which latter remains more fixed in proportion to the amount of effusion and degree of distention. As the effusion augments, the enlargement of the side becomes the more obvious to the eye during the respiratory act, the want of symmetry being apparent in whatever position the side is viewed from; but the amount of difference should be ascertained by measuring the chest horizontally with a piece of tape. Having made the tape, or riband, to meet at the middle of the lower end of the sternum, it should be taken at the precise point of its crossing the spinous processes of the vertebræ, and the difference of length between the two sides will give the amount of enlargement; recollecting, however, that the right side of an adult is about one third of an inch larger than the left.

33. *i. Displacement of the parts and organs bounding the effusion* becomes more and more manifest as the amount of fluid increases. LARRENEC, and many after him, have remarked that the intercostal spaces on the side of the effusion do not present their usual depressions, and that they are sometimes, especially in chronic cases, equal with the surface of the ribs, or even more prominent than they are; but this sign is hardly perceptible in acute cases, unless in the more asthenic states, and when the patient is thin or emaciated. In such cases, Dr.

WILLIAMS has noticed an evident fluctuation, which, however, is a rare occurrence. The smoothness of the side, from the yielding of the intercostal muscles and consequent obliteration of the spaces, as well as the yielding of the diaphragm, and the pushing before it of the viscera of the upper regions of the abdomen, are remarkable when the effusion is great, and are ascribed by Dr. STOKES to paralysis of these muscular parts, consequent upon the inflammation of their serous linings. "The true explanation," he remarks, "of the protrusion of the intercostals and diaphragm will be found to be that they are affected by paralysis following inflammation of a contiguous structure—that their contractile powers are lost, and that hence they yield easily to a pressure, which in their healthy state (as in vesicular emphysema, in hydrothorax, and the first stage of pleurisy) they effectually resist." (P. 464.)

34. Displacement of the organs more immediately adjoining the effusion, especially that of the heart and of the liver, is one of the chief indications of the existence and of the amount of liquid effusion into the pleural cavity, and was first noticed by Dr. STOKES and TOWNSEND. When effusion is considerable in the left side, the consequent displacement of the heart renders its recognition easy. In this case the pulsations of the heart are felt and heard most distinctly under or to the right of the sternum, or as low as the epigastrium, instead of between the cartilages of the fourth and sixth left ribs. If the effusion be on the right side, the liver is pushed down much below the margins of the ribs, and its position is easily traced by percussion and by the touch. It may even be pushed so far as to form a tumour in the abdomen, and hence lead to a serious mistake in the diagnosis, if the symptoms and signs referrible to the thorax be not duly investigated. When effusion in the right cavity is very great, the heart may also be pushed farther than usual to the left, and it may be felt beating to the left of the nipple, or even below the axilla. The mediastinum may also be displaced by a copious effusion, so that a dull percussion sound will be given out over nearly the whole of the sternum, and even for half an inch beyond it upon the sound side, owing to the mediastinum being pushed to this side by the effusion, which thus occupies the space behind the sternum. The dulness on percussion in these cases is most evident below the juncture of the second rib with the sternum. The above displacements may also be caused by air in the pleural cavity, but in this case the tympanitic sound would be present instead of dulness.

35. *k. The motions and sounds of the healthy side*, especially when compared with those of the affected side, indicate either no sign of disease, or an increase of the signs of healthy action, owing to the increased work performed by the sound side. This side moves more fully and rapidly than usual, and the respiratory sound is so loud in it as to resemble the respiration of children.

36. *l. Old, or even recent, adhesions* very remarkably modify the physical signs of pleurisy. When the adhesions are loose, or are stretched by the effused fluid, so as to form bands traversing the effusion, or cells filled with fluid, the lung may be thereby kept at a moderate dis-

tance from the parietes of the chest, and ægophony would thus be continued as long as this state continued. Where the adhesion is extensive and close, fluid poured out in the vicinity will compress one part of the lung, and stretch and ultimately compress the part adjoining, in or near the place of adhesion. Thus, as not infrequently observed, adhesions may be found in the upper regions of the chest, and the fluid effusion in the lower parts may be so great as to press the lungs against the upper portion, and there occasion a loud bronchophony and bronchial respiration transmitted from the large tubes by the adhering dense column of lung; and thus the case may be mistaken for one in which cavities exist underneath this situation; but the prominence of the intercostal spaces, the dulness on percussion, the enlargement of the side, and the displacement of parts, as above described (§ 32, *et seq.*), will readily distinguish its real nature.

37. In rarer instances, the pleura of the upper and posterior parts of the lung may be affected, and that of the inferior portions may be adherent to either the diaphragm or lower walls of the chest. In these the lung will be pressed, by effusion into the upper and posterior parts, against the anterior or other portion of the walls of the thorax, according to the seat of effusion, and to the manner in which the fluid is bounded by the adhesions or false membranes; and the sounds will be tubular, loud, or clear, or otherwise vary, with the part of the lung thus pressed to the sides of the chest, and with the proximity of the larger bronchial tubes; and a more or less loud bronchophony will also be heard.

38. *C. Consecutive Changes in Acute Sthenic Pleurisy.*—If inflammatory action subsides in consequence either of the treatment or of the effusion which takes place, *absorption* of the fluid and of the lymph usually results, and the compressed lung expands under the efforts of respiration in proportion as absorption proceeds. The signs evincing the increased effusion gradually disappear; and ægophony and the sound of respiration return in the situations, generally the upper parts of the chest, where they were last heard. With the return of these, the side assumes its natural appearance, and a gradual improvement takes place of the sound on percussion. In modern cases, as Dr. WILLIAMS remarks, the fluid is absorbed before—indeed, long before—the lymph or albuminous matter is removed; and when the pleural surfaces covered with this matter come together, a rubbing or rustling sound is sometimes heard, which soon ends in the adhesion of these surfaces by bands, or by more continuous false membranes. If these false membranes are formed after the fluid has been removed, and the lung has recovered its full expansion, they are adapted to its free motions, which are not materially interfered with by them. Hence adhesions are often formed, which are lengthened in the lower parts of the chest, where the lungs descend somewhat as the ribs rise, and which are short in the upper parts, where the lungs more closely follow the movements of the parietes.

39. In severe cases, the inflammation continues after the effusion has become abundant; and not only increases or perpetuates the fluid

effusion, but also throws out “albuminous matter in various conditions, which by its present qualities or subsequent changes may produce a variety of prejudicial effects, all tending more or less to interfere with the restoration of the organs to a healthy state.” These consequences arise from the continued or unsubdued inflammation, whether it has been imperfectly treated, or entirely neglected; and they furnish strong proofs of the value of the physical signs, which are never absent, and which rarely fail to point out the existence of these consequences. They will come more appropriately under consideration under the heads of *Chronic Pleurisy* (§ 63, *et seq.*).

40. *D. Termination of Acute Sthenic Pleurisy.*—The most frequent terminations of this form of pleurisy are, 1st, by resolution; 2d, by passing into the chronic state; and, third, by fatal asphyxia.—*a. Resolution* may be complete, the effused fluid and the false membranes being absorbed, cellular adhesions being the only traces left of the disease, or it may be incomplete. In this latter case, the fluid effused is absorbed, but the false membranes remain, undergo changes, and occasion phenomena which will be noticed when the *second* of these terminations are considered.—*b. Death by asphyxia* may occur in the most severe cases, either in double pleurisy, or in the single state of the disease when the effusion is rapid and very great; but this termination is much more frequent in pleurisy than in pneumonia. It is, moreover, very rare in the acute stage and simple form of the disease: it occurs chiefly in the chronic stage, and in the more complicated states.

Before I proceed to describe the changes observed in the pleura and in the matters thrown out on the surface of this membrane after inflammation of it, I shall first notice the several states or forms of pleurisy which differ from that which has now been described, as being the more common type of the disease. Certain of these, indeed, differ from that just considered in very little farther than in the seat or limitation of the disease, or in the stage, period, or continuance of it; and hence the necessity of considering them all in close connexion.

41. ii. DRY PLEURISY—the *Pleurisie sèche* of ANDRAL.—*a.* This state of the disease deserves notice chiefly because it has been particularized by Dr. STOKES and M. ANDRAL; for it can hardly be considered a distinct form, but rather as being particular periods, of pleurisy modified, more or less, by peculiarity of constitution and by the grade of inflammatory action. Dr. STOKES remarks that this term may be applied to that form in which nothing is effused but lymph. The characters of this state, in general, are, that the constitutional and local distress is comparatively slight, that organization rapidly advances, that the sound is clear, or nearly so, on percussion, the phenomena of accumulated effusion being wanting, and that the friction signs are evident. Dry pleurisy occurs, according to these writers, as an original and uncomplicated disease, or as consecutive of fever, erysipelas, or diffuse inflammation. It may be associated with or succeed to any of the diseases of the lungs, or occur as a complication of cardiac or hepatic disease. The circumstances in which I have met with it, in the

least equivocal form, are either associated with, or consequent upon, acute rheumatism, acute hepatitis, and pneumonia.

42. *b. The physical conditions of dry pleurisy* Dr. STOKES believes to occur in two stages of the ordinary disease, namely, in the earliest periods, before effusion takes place; and in the latter stages, when the liquid effusion is absorbed. In the first case, the duration of the friction phenomena depends on the rapidity of effusion; in the second, on the vigour of the constitution which influences the process of organization. At the commencement, pain is often felt in or near the situation of the inflammation, but it soon subsides. The characters of the friction-sound, generally soon afterward heard in the situation of the pain, are various; but this sound always conveys the idea of two rough or dry surfaces moving uninterruptedly upon each other. It accompanies inspiration and expiration, but it may be absent during ordinary breathing, and yet become manifest on forced respiration. In some instances the rubbing sensation is felt by the patient for a long time, but the sound may often be heard long after he ceases himself to feel the obstruction. Dr. STOKES states, that the friction-sound in the early stages of the simple disease, or immediately after the absorption of an empyema, is often accompanied by a rubbing sensation, perceptible to the hand. Like the former sign, this may be absent during ordinary breathing, but become manifest when the patient inspires deeply. In the progress towards cure, this is the first of the physical signs to subside; it is apparently connected with the least organized state of the effused lymph.

43. The duration of the friction-sound, depending upon the absorption of the fluid and the rapidity of organization, varies remarkably in different persons; it is comparatively short in the young and robust; while in the feeble and cachectic it may continue without changing, especially when the disease is consecutive or complicated, longer than a month. It is rarely heard, or continues but a short time, at the commencement of pleurisy, attacking the cachectic, or complicating febrile maladies. When, however, it follows the absorption of an effusion, it may continue from several days to some weeks. It is heard most distinctly over the middle parts of the chest. The friction is rarely heard when the dry state of pleurisy is consequent upon pneumonia with hepatization of a considerable portion of the lung. It is more distinct when the pleurisy is consequent upon, or complicated with, acute hepatitis. When pleurisy is associated with pericarditis, the rubbing sounds seem double, but the combination of that caused by the action of the heart, with that following respiration, often causes a confusion, which requires attention and practice to distinguish and duly recognize.

44. *c. The causes of the friction-sounds* have been differently stated by pathologists. These sounds, variously modified with the nature of the case, have been heard in certain states of inflammation of the pleura, pericardium, and peritoneum; and as they have not been heard in those states which are attended by a copious liquid effusion, but in that in which an unorganized lymph is presumed to exist on the

surface of the inflamed membrane, so they have been viewed by M. RENAUD, Dr. CORRIGAN, and Dr. STOKES as being caused by the presence of this lymph in the situations where these sounds are heard. Still this cause admits of doubt; for the *creak*, or *leather-creak*, admitted to be one of these friction-sounds, is rather to be viewed as given out by the membrane itself in certain morbid states of it, than by the friction of the opposite surfaces when covered by unorganized lymph. The fact, however, of Dr. CORRIGAN having produced the sounds in question by rubbing two portions of the inflamed membrane one upon the other, may appear conclusive of this point; still, I believe the matter still to require farther examination.

45. *d. The existence of dry pleurisy*, it should be mentioned, even as a *stage* of pleurisy, has been doubted very recently by a no less distinguished pathologist than Professor HASSE. He remarks, that the attempt has been made to reckon the progress of pleurisy by defined stages; first, the period of dry inflammation, which is of shorter or longer duration, and comprehends all the changes observed in the pleura and sub-serous cellular tissue (see § 112), but without, as is supposed, any serous effusion. Now, he adds, that he has never encountered this dry stage as described, having always, even at the very outset, found the serous fluid somewhat, however slightly, augmented in quantity, and marked by its deep yellow tinge and its increased consistency. There were, likewise, present those grayish or yellowish points, the initial and quickly-expanding rudiments of membranaceous formations. "The so-called *dry pleurisies* of ANDRAL (*Clin. Med.*, 4mo edit., t. iv., p. 405)," he continues, "are, therefore, probably to be understood in a comparative sense only—effusion too scanty to be detected by physical signs during life. Such a ground of distinction is, however, obviously opposed to the strict principle of pathological anatomy." The second stage has been viewed as eminently that of effusion, which, although not confined to any one period, is not sufficiently copious and characteristic to constitute a secondary and distinctive stage until the original inflammation has become thoroughly developed. But to divide the period of effusion into two stages, and thus to attempt to discriminate between the development of liquid effusion on the one hand, and of coagulable lymph and adventitious membrane on the other, are discordant with the process which gives rise to these productions. The third period has been considered to be the organization of the plastic exudation. This, however, does not take place at any particular stage, nor is it a process to which every form of plastic effusion is necessarily subject. It would be difficult to reconcile, in this arrangement, those pleuritic exudations which exhibit traces of organization after the first twenty-four hours, with those in which the organizing powers have been ineffectually exerted for weeks or months. While, therefore, this division might seem justified in some instances by the procession of morbid phenomena, it would in others be quite inapplicable. It would probably be preferable to consider the secondary changes in pleurisy according to the degrees of intensity

of the primary inflammatory act, and to the rapidity with which they ensue upon this act.

46. *E. Pleurisy as above considered*—whether it be attended by little or no liquid effusion at an early stage, by a rapidly increasing and abundant effusion, or by more or less organization of the exuded lymph—generally presents a *sthenic character*, more especially when it occurs primarily, and in a previously healthy constitution. It then, particularly in the young, robust, plethoric, or sanguine temperament, is accompanied with highly inflammatory symptoms, local and constitutional; runs its course frequently with great rapidity, and evinces a greater tendency to the organizing or formative process, even although effusion, to a great extent, may rapidly supervene. The *sthenic character* may also exist, although in a much less marked degree, in more delicate or even in lymphatic subjects, especially when the disease is primary, but it is then attended by much less fever and less severity of local suffering, the symptoms more nearly approaching the state of the disease next to be noticed. The *sthenic character* may likewise be evinced in pleurisy consecutive of, or complicated with, pneumonia, hepatitis, pericarditis, or acute rheumatism, in all which, although it sometimes assumes more or less completely, or approaches to, the *asthenic character*, the *sthenic* is more frequently observed, unless in the aged, the debilitated, and cachectic.

47. iii. *ASTHENIC PLEURISY.—Pleuritis Nervosa*, RICHTER; *Cachectic Pleurisy*.—This form of pleurisy is generally met with in persons who have been debilitated by previous acute or chronic diseases; in the cachectic, or those subject to some constitutional vice; in persons whose constitutions are broken down by intemperance and dissipation, and more especially in the course of other maladies in which the circulating fluids are contaminated either by the absorption of morbid matters, or by interruption of any of the eliminating or depurating processes. It thus not infrequently supervenes in the course of, or during convalescence from, typhoid or adynamic fevers, exanthematous fevers, puerperal fevers, erysipelas, organic changes in the kidneys, phlebitis, diffuse inflammation, or spreading and diffuse suppuration, and consecutive abscesses. In all these, effusion is more or less rapid, the dry stage hardly or not at all exists, and albuminous exudations either are not formed into membranes and adhesions, or do not become organized unless a change is produced during the course of the disease in the states of vital power and of vascular action. Indeed, in the majority of cases of *asthenic pleurisy*, the albuminous portion of the exudation is more or less mixed with the serous fluid, the fibrinous or fibro-albuminous character not being present.

48. This form of the disease is seldom attended by acute or painful local symptoms. It is generally *latent*, and often effusion is far advanced, or has long existed before the disease is detected. It is rarely a primary affection, is most frequently associated with some other disorder or structural change. It is sometimes very sudden in its occurrence, and indicated at first by the shortness and frequency of respiration, by the position of the patient, and the sinking of the powers of life, rather than by

local distress or pain, or by febrile symptoms, which, if they be present, are usually of an adynamic character. This state of pleurisy, as may be expected from its nature and the circumstances in which it appears, is always removed with great difficulty, or not removed at all, especially if copious effusion has taken place before it was detected. It may supervene in the course of the maladies just mentioned (§ 47), and escape detection until dissection after death discloses its existence, although attention has been directed to its contingent appearance, especially when the effusion has been small, or when it has taken place shortly before death. I have thus met with it in the last stage of malignant or infectious puerperal fevers, in open cancer of the mamma, confluent smallpox, &c. I have seen albuminous exudations covering the pleura in some of these cases, but the serous effusion was abundant, and the membranes formed by these exudations evinced no indication of incipient organization.

49. iv. *LATENT PLEURISY.—Pleuritis Occulta*, RICHTER.—The term *latent* has been applied to pleurisy when it takes place without pain in a situation where it can be referred to the pleura. And this state of the disease is more frequently associated with the *asthenic* than with the *sthenic character*; or, in other words, *asthenic pleurisy* is much more frequently *latent* than *sthenic pleurisy*. M. CRUVEILHIER supposes that this state of the disease is more frequent than any other. The numerous instances of adhesions between the opposite surfaces of the pleura found on dissection of cases, in which no symptom of pleurisy had been complained of, appears to justify this opinion. Still we often hear of instances of pain in the side ascribed to pleurodynia, or to rheumatism of the intercostal muscles, where a more accurate examination may have detected pleurisy. Besides, pain is often present for a time, and either overlooked or forgotten, or ascribed to some other than the real cause.

50. *Latent pleurisy* may be either *acute* or *chronic*. In its latter state, it will be noticed hereafter. It may be either *primary* or *consecutive*, or associated with some other disease. Pleurisy may be *latent* in either of two ways, owing, 1st. To the absence of all pain whatever. 2d. To pain being felt in some part remote from the thorax, and suggesting the existence of disease in some other quarter. This *second form* of latent pleurisy has hitherto not been noticed by writers; but I have met with several instances of it, and recently with three cases which were primary and uncomplicated. In all these the pain was referred to the iliac region of the same side, no pain being felt in the chest, at any part, upon a full inspiration, or when coughing, although it was excited in that remote situation. In most cases of latent pleurisy there are chilliness, thirst, heat of skin, especially in the trunk, dryness of the general surface; and, as effusion becomes copious, shortness of breathing, with more or less difficulty or oppression, upon the least exertion. This form of pleurisy often affects children and old persons; and in both classes of persons it is frequently associated with catarrh or influenza. Indeed, so often is this complication met with in these subjects, that a careful examination of the chest should be made in

all cases of severe catarrh or influenza affecting them.

51. *V. PARTIAL PLEURISY.*—Circumscribed or partial pleurisy may occur *primarily* or *consecutively* of other diseases, but much more frequently in the latter than in the former state. Circumscribed or limited pleurisy may also be attended either with *adhesions* only, or with *effusion*, adhesions, however, of various extent also existing in the latter class of cases.—*A.* The *adhesive form of partial pleurisy* is very frequent, and is commonly consecutive of tubercular formations in the lung, of either of the forms of pneumonia, and of inflammatory irritation of any kind in the vicinity of the part of the pleura becoming thus affected. It is a very usual consequence of tubercular depositions, softened tubercles or cavities, when either approach to the surface of the lung, the pulmonary pleura then becoming inflamed, and throwing out lymph which agglutinates it to the opposite costal or diaphragmatic pleura, most frequently to the former at its upper regions. The pleuritic affection is in these cases often slight, but it is seldom latent to the close observer. It is generally indicated by more or less pain, uneasiness or tenderness in or over the part affected; by a feeling of constriction or tightness, by frequent superficial breathing, and by diminished motion of the ribs in that situation; somewhat increased dullness on percussion, increased pain or uneasiness upon stretching or exerting the adjoining muscles, and a greater intolerance of a strong percussion over the part than in any other place, are often, also, present. The pain is sometimes sharp, evanescent, and even so slight or brief in duration as hardly to be noticed or recollected. This form of partial pleurisy is often salutary in its effects, in respect of the tubercular malady, of which it is so generally a consequence, inasmuch as the adhesions between the opposite pleural surfaces prevent ulceration and perforation of the pulmonary pleura, and the escape of the tubercular matter into the pleural cavity. Although this state of the disease is sometimes latent, it is less frequently so than has been stated by some writers, it being rather overlooked, owing to the slightness or evanescence of the symptoms just mentioned.

52. *B. Partial pleurisy with effusion* is much less frequent than the foregoing.—(a) It is commonly a consequence of a more general state of the disease, in the course of which adhesions have taken place between the opposite surfaces in one part, and effusion or even supuration in another. In some instances, the pleurisy attacks a person who has previously been the subject of this disease, and in whom adhesions of greater or less extent already exist; and this subsequent attack affects merely that portion of the pleura which is non-adherent; the adhesions limiting the extension of the inflammation, and bounding the liquid effusion, or purulent formation. Partial pleurisy, accompanied with liquid or puriform effusion, may occur in any situation; but its nature can seldom be ascertained with any degree of certainty during life.

53. (b) The above observation applies to *interlobular pleurisy*, or inflammation, and its consequences affecting the opposite surfaces of

two corresponding lobes of the lungs. This particular form of partial pleurisy is rarely primary, but is generally consequent upon the more general state of the disease, or upon tubercles in the lungs or pneumonia. The *vomicæ*, so often said to have been found in the lungs, have very probably been puriform collections between the opposite pleural surfaces, circumscribed by adhesions, in this and the preceding states of partial pleurisy.

54. (c) The question has been put by M. CRUVEILHIER, whether or not a *costal pleurisy* can exist independently of a *pulmonary pleurisy*, or the latter exist without the former. BICHAT believed that it could not, and contended that the inflammation always extended from the one surface to the other continuously, or without any interruption at the non-adherent parts. I am convinced, however, that this is not the case, unless in the asthenic or spreading form of the disease; but that the inflammation originating in either surface is followed by an exudation of lymph which acts as an irritant, when brought in contact with the opposite surface, and inflames this latter; and thus inflammation, or adhesion, or even effusion, is often developed in the opposite surfaces without the continuous extension of the morbid action over the intervening, non-adherent, or unaltered part of the membrane.

55. It has been supposed by some writers that inflammation of the pulmonary pleura is not attended by pain, and that pain is felt only or chiefly when the costal pleura is implicated. This opinion has been considered to derive much support from the different anatomical connexions of the two portions of this membrane. This distinction, however, is by no means determined; farther and more precise observation is required before an opinion can be given respecting it.

56. (d) *Costo-pulmonary pleurisy* may be attended by liquid, or sero-albuminous, or puriform effusion or collection, limited by adhesions to a smaller or larger space, as shown above (§ 52). The circumscribed purulent collections—the *empyema necessitatis* of various writers—sometimes met with, and that point externally, are of this kind.

57. *C. Mediastinal Pleurisy.*—This form of circumscribed pleurisy has been considered, as far as the subject admits of consideration, in the article MEDIASTINUM. It is unnecessary, therefore, to add more at this place than to remark, that inflammation may originate in that portion of the pulmonary pleura in contact with the mediastinum, and extend to this latter, forming adhesions between them, and giving rise to liquid or puriform effusion, which may be bounded by these adhesions. In cases of considerable duration, the liquid collection may assume puriform and encysted appearances. The exact nature of these cases is seldom accurately ascertained during life; for they are most frequently secondary and complicated with pneumonia, or with tubercles in the lungs, or even with pericarditis. The symptoms of this state of the disease, as far as they are known, are the same as those stated in the article MEDIASTINUM (§ 3, *et seq.*).

58. *D. Diaphragmatic pleuritis* is of frequent occurrence, especially in the course of inflammations of the liver and peritoneum, and even,

although much more seldom, of the liver and of the spleen.—(a) This form of pleurisy may be consequent upon either acute or chronic disease of these parts, especially upon the former. I have at another place (*see* LIVER, § 41, *et seq.*) remarked upon the not unfrequent extension of inflammation from the liver to the diaphragm and diaphragmatic pleura, and even also to the costal and pulmonary pleura; and, although this occurrence is sometimes met with in connexion with abscess of the liver, it also not unfrequently takes place in the course of sero-hepatitis, or in cases of inflammation of the superior serous surface of the liver, and of partial peritonitis in the superior abdominal regions. I have met with several cases of acute sero-hepatitis in which the inflammation rapidly extended to the pleura, the disease consisting, during the greater part of its course, of hepatitis complicated with pleuritis.

59. It is very rare, however, unless in cases of this kind, that is, in those consequent upon inflammation of some one of the abdominal viscera, that pleurisy is limited to the diaphragmatic pleura; and even in those it soon extends, more or less, to the pulmonary or costal pleura of the same side as that on which the viscus first attacked is situated. This mode of extension is not, however, always observed; for, in a case at this moment attended by me, but which I did not see at its commencement, there are chronic hepatitis, with tenderness in the region of the liver, effusion into the peritoneal cavity, and pleuritic effusion into the left pleural cavity, the heart being pushed towards the right side of the chest.

60. (b) The symptoms of diaphragmatic pleuritis differ but little from those of the more usual states of pleurisy. Generally, however, when this portion of the pleura is more especially affected, there are acute pain, augmented by inspiration, by physical efforts, by vomiting, or even by the eructations of flatus, and seated at the base of the thorax on either side, or about the attachments of the diaphragm to the thoracic parietes; anxiety, difficulty of breathing, or orthopnoea, the patient being obliged to sit up, with the trunk of the body bent forward; an anxious and distressed expression of the features; sometimes nausea or vomiting, and singultus; and considerable symptomatic fever, occasionally with delirium. When effusion is considerable, or collections of sero-puriform or purulent matter are present between the base of the lungs and the diaphragm, this latter is pressed downward, and considerable fulness, with dulness on percussion, is observed in the hypochondrium of the affected side, and thus the semblance of an enlarged liver or spleen may be occasioned. When the liquid collection is completely circumscribed between the base of the lungs and the diaphragm, the diagnosis is usually difficult. The antecedent symptoms, especially pain or stitch in the side, with symptomatic fever, ushered in by rigours, will indicate the nature of the disease. Complicated cases, however, may occur in which the diaphragmatic pleura is affected on the one side, and the peritoneum, or some infra-diaphragmatic viscus, on the other, and be attended by great difficulty of ascertaining the exact seat and extent of mischief; but a careful examination of the physical signs and

the symptoms during the progress of the disease, and a due recollection of the fact that inflammations not unfrequently extend from one side of the diaphragm to the other, especially from the peritoneal to the pleural surface, will often aid the physician in his diagnosis. In some cases of diaphragmatic pleurisy of the right side, excessively acute pain along the margins of the right side; short, anxious respiration, jaundice, protrusion of the liver downward by the fluid effused between the diaphragm and lungs, and much symptomatic fever, were the most prominent symptoms.

61. vi. DOUBLE PLEURISY.—a. Pleurisy rarely attacks both sides of the chest at the same time and in a primary form; but instances of this double disease occasionally present themselves, especially in a secondary form, and consecutively of adynamic, or malignant, or of exanthematous fevers, of erysipelas, or of those states of constitution which have already been noticed as imparting an asthenic character to pleurisy, more particularly morbid states of the circulating fluids. In double pleurisy, both sides of the thorax are not always affected to an equal extent, nor are the inflammatory products always the same, in respect either of the effusion or of the more consistent exudation. One or other may be much more abundant in one side than in the other, and even be otherwise modified or different; and very generally the patient is carried off, either by asphyxia, or by the effect upon the powers of life occasioned by the extent of lesion, before effusion has taken place in both pleural cavities to a great amount, or before the false membranes which may have been exuded have presented any advancement towards organization.

62. b. The symptoms and signs of double pleurisy, in most instances, readily evince the extent of the disease. In some cases, however, there is difficulty in determining, 1st, the existence of pleurisy; and, 2d, its presence in both sides of the thorax. When effusion takes place, then the bronchial respiration, ægophony, and the obscurity of the sound, can leave no doubt as to the nature of the disease. The sound emitted on percussion is attended by greater difficulty, because the means of comparison are wanting. Pain is not always a certain symptom, as it may be wanting in either side, although the amount of disease may be even greatest in the side where it is not felt. Generally, however, the history of the case, the state of respiration, the positions of the patient, and the constitutional symptoms, viewed in connexion with the physical signs, will indicate the extent of the malady. This state of pleurisy is much more dangerous than the ordinary forms; indeed, the patient may be carried off by it, aided by some other associated complaint, before the more advanced lesions have supervened, and even before the amount of effusion or the character of the symptoms had admitted of the recognition of the full extent of the malady.

63. vii. CHRONIC PLEURISY.—EMPHYEMA.—Pleurisy assumes every grade of severity, of activity, and even of duration. It may be most acute, as respects the degree of suffering, and the rapidity of its progress; and it may be most latent in its character, and slow in its course, and in the progress of the suc-

cessive changes attending and consequent upon it. Between the extremes of these, the intermediate grades of morbid action and duration, and shades of character, are innumerable. *Chronicity*, therefore, in respect of pleurisy, is, perhaps, more of a conventional term than as regards almost any other malady. The *chronic state* of this disease is commonly consequent upon the acute, when this latter has been either neglected or improperly treated; but it is also sometimes primary, or rather the advanced or prolonged state of a pleurisy which has commenced in a latent and silent, perhaps also in a slight or sub-acute form, and has continued thus to advance until the amount of effusion has given rise to phenomena such as have been described above (§ 30, *et seq.*), and as could not be neglected any longer by the patient or overlooked by the physician. Chronic pleurisy may even be an *intercurrent* malady, or supervene secondarily in the course of some other disease, although not so frequent as acute pleurisy. Thus it may occur in the course of chronic disease of some contiguous viscus, as of the lungs, liver, spleen, peritoneum, stomach, &c., or of malignant affections of the mamma, or diseases of the skin, &c.; while the acute states of pleurisy most commonly occur in the course of malignant or adynamic, exanthematous, and other fevers, or of inflammation of adjoining organs. Chronic pleurisy may thus, as well as in other forms of succession, be *complicated* with some other disease; indeed, it frequently becomes thus associated from the very circumstances of its duration.

64. Chronic pleurisy, in the state of full development, is attended by great effusion of fluid; and to this condition, whether it be the consequence of a violent attack, or of a sub-acute, or of a latent state of the disease, the term *empyema* has been given, although the composition of the fluid effused is often very different from pus; it being more frequently serous, sero-albuminous, or sero-puriform, or sero-sanguineous, as will be more fully shown in the sequel.

65. Although I agree with Dr. WILLIAMS that the transition of the acute to the chronic state is so indefinite, and the symptoms of the recent disease sometimes have so little of an acute character, while that of a long duration occasionally manifests so much greater an intensity of irritation, that the terms acute and chronic would seem to be less applicable to pleurisy than to other inflammations, still I cannot consent that the distinction in question should be altogether set aside. I readily, however, subscribe to the circumstance that much of the difficulty connected with this distinction is to be ascribed to the anatomical relations of the pleura: this being a shut sac, it is liable to have its acute inflammations rendered chronic by the retention of the inflammatory products; and the chronic state is equally liable to be excited into an acute state by the irritating and distending influence of these products, more especially the fluid products. Still, differences in character or form, in connexion with duration, are very apparent in many cases; in the prevalence of high inflammatory fever, severe local suffering, and rapid progress in some; or in the absence of fever, or in the existence of hectic or remittent fever, with but little or

slight local suffering or discomfort, and slow progress or long duration in others; in the sthenic character of vascular action and vital power in many; in the asthenic condition of both action and power in some; and in the varying grades of pain, of irritation, and of sympathetic disturbance in all. These differences can hardly be described in all their phases of existence as they are presented to our view in practice; but they require to be pointed out in such a way as will most remarkably fix our attention, and render them safe guides in devising our indications and means of cure.

66. *Effusion* being the characteristic condition of *chronic pleurisy*, as well as of the advanced state of the most frequent form of *acute pleurisy*, it follows that all that has been stated above with reference to the latter (§ 24, *et seq.*) is equally applicable to the former. The disease, whether denominated acute pleurisy with effusion, or chronic pleurisy with effusion, or empyema—or whether or not the liquid be purulent, or sero-albuminous, or of any other description hereafter to be noticed—is attended by the same local and physical phenomena and signs, however much the states of vascular action, of vital power, and of constitutional disturbance may differ, in each case, with its duration and progress. *Chronic effusion*, even to the extent of compressing the lung and displacing the mediastinum, and even the diaphragm, may exist without distressing constitutional symptoms, which may either have subsided, or, in fewer cases, never existed. Dr. STOKES truly remarks that, if we separate the *physical signs*, we find nothing characteristic in the general symptoms alone. Hectic may or may not be present; and no characters of the cough, expectoration, respiration, decubitus, or, with a single exception, the appearance of the patient, are sufficient to distinguish this from other diseases of the lung. This exception is the dilatation of the side and intercostal spaces. But if, in addition to the symptoms of pulmonary irritation and obstruction, as shown by cough, shortness of breathing, dyspnoea, increased by exertion, or by lying on the affected side, and by a sense of fulness and oppression referred to one side, which is often oedematous, the physical signs of fluid accumulation, compression, displacement, &c., be also present, we may safely diagnosticate the disease.

67. In certain cases the general symptoms are nearly wanting. Instances are not rare of persons with copious effusion of considerable duration to be without fever, pain, or local distress; to look tolerably well, and to have good appetites; to lie nearly equally well on either side, and even to pursue their usual occupations, when these are not laborious. The physical signs are hence of the utmost importance in chronic pleurisy; indeed, of greater value in this than in any other thoracic disease. Most cases of bronchitis, of pneumonia, and of phthisis can be, at least, recognised, as Dr. STOKES remarks, without these aids; but such is not the case with pleurisy; and it is fortunate that its physical signs are more simple, numerous, and striking than those of any other of the complicated diseases of the lung.

68. When chronic pleurisy is not accompanied by much fever or pain, the patient may not be obliged to keep his bed. He complains only

of shortness of breathing on exertion; and he often pursues his usual occupations. He merely believes himself indisposed, and considers that he is not the subject of serious disease, until the pallor and emaciation of his features, the general loss of strength and flesh, the coldness of the extremities, the short, suppressed cough, the frequent and short respiration, increased on the least exertion or mental emotion; the loss of appetite, the rapidity of his pulse, especially during evening exacerbations, of hectic; and the inability of lying on any other than the same side, attract his notice, and direct the attention of the physician he consults to the nature of his complaint. These symptoms having suggested the seat of the mischief, an examination of the chest readily discloses its nature and extent.

69. *B. The physical signs of chronic pleurisy* are those already described (§ 26, *et seq.*) as evincing extensive fluid accumulation in the pleural cavity; but they become, with several of the general symptoms, much modified by the duration of the effusion, and by the changes in the pleura and lung. The state of the liquid effusion also modifies the course and phenomena of the disease; and hence it is necessary to notice briefly those changes which thus influence the character of the malady. When pleurisy has continued for some days, alterations take place not only in the more consistent exudation, but also in the fluid effused. These alterations depend much upon the diathesis of the patient, and the states of vital power and vascular action; and although some of them may be inferred to be present by the symptoms and signs during life, yet others are, owing to their nature, incapable of being indicated until disclosed after death.

70. (*a*) In healthy, young, and robust persons, lymph of a highly organizable quality is thrown out upon the inflamed surface, of greater or less thickness, with a serous effusion; and this lymph, forming a layer, or false membrane, over the surface, although diminished by absorption, becomes more dense as it is organized, and thus restrains the expansion of the lung, and impedes the absorption of the accumulated serum. In cases where the membrane is less dense or thick, the expansion of the lung and the absorption of the fluid may proceed, especially when vital power is not defective, until ultimately the fluid is removed, and the lung acquires very nearly or altogether its natural expansion. In this case adhesions, cellular, partial, or otherwise, may form, and the functions of the lung not be materially impeded (see § 115).

71. (*b*) In other cases, by no means different from the above, or varying only in the states of vital power and vascular action, and generally of a less active inflammation and more prolonged duration, organization proceeds slowly, and the false membrane is of a more dense and rigid nature. Consequently, the lung is prevented from expanding, even although the fluid effused be partly or nearly altogether absorbed. In many cases, especially in those of considerable duration, the false membrane covering the lung shrinks or contracts in its superficial extent, in the manner stated when describing the changes consequent upon peritonitis; or like cicatrices after burns

of the skin, and thus not merely prevents the expansion of the lung, but actually compresses this organ still more closely. In more chronic cases the membranes formed on the pleura assume a state of cartilaginous induration, or become more or less extensively ossified, or they may be cartilaginous in parts and ossified in others. These changes often coexist with the shrinking just noticed, and are to be ascribed in part, in some cases at least, to the irritation produced by the effused fluid on the surfaces enclosing it.

72. (*c*) In some cases, when the vital energy is insufficient to enable the inflamed surface to throw out a readily organizable lymph, the exuded matter assumes a curdy appearance, of greater or less thickness, almost solely albuminous, and presents much less of a fibrinous character than in the foregoing cases; and the fluid part of the exudation is turbid, or contains loose shreds or pieces of albumen (see § 116, 117). In some instances a false membrane of some density is found covering the inflamed surface, but it is imperfectly organized, or presents no traces of organization. In other cases, a coating of albumen, without adhesion or organization, covers the pleura, the fluid effusion being turbid, serous, or sero-albuminous, or otherwise changed or coloured, according as colouring particles of the blood may be exuded. This class of cases is more frequently of much shorter duration than the foregoing classes, are always asthenic, and are more closely allied to the acute asthenic form of the disease (§ 47), being more prolonged instances of that form.

73. (*d*) The albuminous or nutritive matter may be thrown out in a more diffused form with the serum; or the formative process, characterizing so frequently inflammations of serous surfaces, may be still less exerted, and a puriform, or sero-puriform fluid only be produced. It is probable that, in some instances, when the immediately preceding state (§ 72) of the disease is much prolonged, the sero-albuminous exudation may pass into a puriform or sero-puriform state. This purulent state of the effused fluid appears most frequently in the most chronic cases, but it also is sometimes observed in the most acute, and is that to which the term *empyema* is strictly applicable. It depends rather upon the state of vital power, or the diathesis of the patient, in connection, probably, with the condition of the blood, than upon the duration of the disease. Dr. WILLIAMS very justly remarks, respecting this state of the disease, that "the solid matter is thrown out in a disintegrated state, utterly insusceptible of organization, and diffused through the fluid in flakes or particles, forming a mixture more or less resembling pus, which is the fluid or empyema. Although in many instances this is the result of a more chronic form of pleurisy than that which forms lymph, and owes its persistence and tendency to increase to the want of vitality in its solid matter, yet we do meet with cases of empyema which arise from very acute forms of inflammation. In these instances the fluid is more strictly purulent, the solid matter being in the form of globules, like those of pus, and seems to be the result of what may be called a suppurating diathesis, in consequence of which all the albuminous products of

inflammation tend to assume a purulent character." It should be remarked, also, that the continued access of air will cause the inflamed pleura to secrete pus instead of coagulable lymph, this membrane being similarly influenced by this cause to other tissues. Whenever pleurisy is consequent upon perforation of the lung, the effused fluid is always purulent.

74. (c) The other lesions which are contingently associated with chronic pleurisy, especially the tuberculous, schirrous, encephaloid or fungoid, and melanotic, generally proceed from their respective constitutional taints: they will receive due consideration hereafter.

75. It is obvious that the above states, into which the lesions of chronic pleurisy may be divided, are not precisely defined in all cases; but that instances occur, owing to changes of vital power and vascular action in their course, in which intermediate conditions, or transitions from one state to another, may be found on close examination. The truth is, that in many instances, even after the acute action has subsided to the chronic state, the retained effusion, owing to the nature and combination of the several elements, may rekindle an acute or subacute state of action, or keep up a continued irritation, which cannot fail of producing a varied series of changes not only in the false membranes, but also in the pleura itself and the subjacent tissues; and that the effused fluid, as well as the surrounding structures, both natural and adventitious, will consequently undergo changes varied in numerous ways, although most frequently presenting the general features now pointed out, and those about to be more minutely described (§ 118, *et seq.*).

76. In some cases the condition of lesion, in respect both of the more consistent exudation and of the fluid accumulation, may be predicated during life from the indications of vital power and vascular action furnished by the patient. The *first* and *second* of these conditions (§ 70, 71) are generally attended by a more sthenic state or diathesis, by less failure of constitutional power, and a stronger grade of vital resistance. The *third* (§ 72) is accompanied with more marked asthenia; with greater depression of vital energy and resistance than the first and second; with more or less of a cachectic appearance, or of a morbid condition of the circulation. The *fourth* (§ 73) of these conditions, or that to which the term *empyema* is more strictly applicable, is generally attended by hectic of a marked character, by night perspirations, and often by various pulmonary symptoms in connexion with physical signs of accumulation of fluid in the plural cavity.

77. When we reflect upon the effects consequent upon the retention of the products of inflammation in the pleural sac; upon the constricting action of the organized false membranes on the lung; upon the irritation caused by the nature of the fluid effusion, and the consequent resuscitation of inflammatory action in acute or subacute states, extending more or less to the parenchyma of the lungs; upon the influence of constitutional diathesis and taint upon the states of vascular action and adventitious productions; and upon the numerous contingencies, intrinsic and extrinsic, moral and physical, to which the patient is exposed,

we may readily infer that chronic pleuritis, if not soon remedied, must necessarily be followed by farther alterations, not only of the adventitious formations, and of the consistent and fluid deposits in the pleural cavity, but also of the lungs, bronchi, pericardium, and parietes of the chest. These successive alterations all tend to impede absorption, and thereby to perpetuate the disease; and are the most important lesions which *complicate* the advanced course of the more unfavourable cases of chronic pleurisy. Nevertheless, absorption does take place in many instances—sometimes even in prolonged cases, especially when vital power and resistance are tolerably maintained, and when the consecutive lesions, or *complications*, about to be noticed are not developed.

78. C. *Signs of Absorption of the Effusion.*—

(a) Many of the cases of acute and subacute pleurisy recover without contraction of the side or depression of the shoulder, such as will be noticed hereafter; but in these cases the effusion is more or less readily absorbed. It is, however, comparatively rare for the fluid to be removed, in the more chronic cases, without these changes in the appearance of the affected side being observed. When the lung is bound down or constricted by the false membranes, as stated above (§ 71), or when it is so condensed by long-continued pressure, or by the extension of inflammation to its parenchyma, as no longer to be capable of expansion, the removal of the fluid accumulation by absorption necessarily occasions, owing to the atmospheric pressure, more or less contraction of the affected side, which, instead of being enlarged beyond the size of the healthy side, now gradually becomes smaller—sometimes very remarkably smaller, than that side. The contraction appears at first in the upper part of the chest; the shoulder being depressed, and, with the whole side, much more fixed than the sound side, which presents the full development and active motions of respiration. As the diseased side contracts, the ribs approach closer together, and sink lower; the scapula is more prominent, and nearer the spine; and the sternum and spinal column are somewhat curved, so as to be concave on this side. While the upper parietes of the diseased side are thus pressed inward, the lower walls are similarly affected; the diaphragm is carried upward, and with it the liver, or the stomach and spleen, according as either side is affected. In cases where the absorption has proceeded far, or has taken place long previously, more especially in children and young persons, the healthy lung becomes so expanded or developed from its augmented function as to press the mediastinum over into the affected side, and thus even to prevent a still greater contraction of the side from occurring. Cases are not very rarely seen in which the heart has been thus pushed either to the right side, or drawn upward to the left, owing to the two causes of absorption of the effusion in the side toward which the heart and mediastinum are drawn, and of expansion of the lung in the sound side. In cases of this kind, the displacement, instead of being the result of liquid effusion, or of a collection of air or gas pushing these parts to the sound side, is caused by the removal of fluid from the affected side, in the manner now pointed out

In a few instances, as remarked by Dr. STOKES, the contraction is confined chiefly to the lower portion of the side, the shoulder not being materially depressed. In those instances, occurring in young persons, in which the sound lung becomes much expanded, the deformity often is much diminished in process of time.

79. M. LAENNEC has insisted strongly on this termination being most frequent after what he terms the *hæmorrhagic pleurisy*, or that state of acute pleurisy in which the fluid effusion is very great, and more or less tinged with blood-globules, and which often becomes chronic owing to the slow removal of the fluid. Although contraction of the chest is most apt to accompany the cure of the most severe cases, or those in which the effusion has been the greatest or most prolonged, yet it is by no means confined, as LAENNEC supposed, to those cases which he denominated hæmorrhagic, or even most frequently consequent upon these; for, as Dr. FORBES has remarked, it is a common consequence of the removal of all fluid effusions of considerable duration, and of purulent collections in the pleural cavity; "and, if other evidence were wanting, we have it in the analogous contraction in chronic pneumonia and phthisis."

80. In some instances the contraction consists chiefly of a flattening of the anterior portion of the side, causing more deformity than diminution of size. In others, the affected side approaches somewhat to a triangular form, "the base of the triangle corresponding to the mesial line, and the apex to the centres of the ribs." One of the first signs of absorption with contraction is the increased prominence of the inferior angle of the scapula. Dr. STOKES thinks it likely that the paralysis of the intercostals and diaphragm, which he believes to accompany pleurisy, has an immediate effect in producing the subsequent contraction, by preventing the expansion of the side.

81. The condition of the side of the chest changing thus from that of dilatation, consequent upon the effusion, to that of contraction caused by the removal of the fluid, it may be supposed that the transition from the one to the other will not be indicated by the form of the chest; and this is really the case in some instances, although in the majority the transition is not uniform, but partial. More frequently the contraction commences at the upper part of the thorax before the dilatation and displacement have entirely disappeared at the lower. An irregularity of the shape of the affected side is hence often observed during the removal of the effusion by absorption, the upper parts being unusually contracted or depressed, while the lower are more or less bulged or dilated. This appearance assists in the diagnosis between consolidation of the lung and progressive absorption of a pleuritic effusion, for which this latter may be mistaken.

82. But the effusion into the pleural cavity may not be to the extent of filling this cavity; it may be partial only, or limited by adhesions and false membranes, as above described (§ 52). In these cases of partial adhesions, the walls of the chest cannot so contract as to accommodate themselves to the vacuities caused by the removal of the fluid. Sometimes slight or irregular contractions may take place; but the

spaces are chiefly occupied by a partial rising of the diaphragm, and expansion of the healthy lung on both sides; and most frequently a portion of the more consistent or albuminous contents of the effused fluid still remain, presenting a curdy or semi-solid state, which is probably ultimately removed when the patient permanently recovers.

83. *b. The auscultatory signs* furnished by a side contracting after chronic pleurisy are of importance, inasmuch as during the progress of the contraction the disease may be mistaken for chronic pneumonia, or consolidation of the lung, or for tubercular diseases of this organ, or even for enlargement of the liver. In many cases, especially when the effusion has been copious and of long duration, the sounds of respiration and percussion continue permanently imperfect, even although the fluid may be completely removed, and they are universally more or less impaired for months after the attack. They thus correspond with the diminished motion of the affected side, and are owing to the same lesions. Dr. WILLIAMS correctly states that an improvement is generally indicated first in the upper part of the chest, and near the spine. With the return of a weak respiratory murmur, and slight resonance on percussion, some degree of vocal resonance may also accompany the removal of the fluid in the upper parts of the chest, "amounting to loud bronchophony, often accompanied with a remarkable buzz; in other parts being merely the diffused vocal fremitus, according to the size of the bronchial tubes, and the degree and permanence of their compression." In some cases of this kind some of the physical signs may mislead, if attention be not paid to all these signs, and to the history of the case; for, as remarked by Dr. STOKES and Dr. WILLIAMS, if at the first time we see a patient with the above signs, and he happen to have bronchitis, we may be induced to believe that the resonance of the voice and the dullness are caused by consolidation from recent inflammation of the lung, or from tubercles; but this error will be prevented by attending to the history of the case and the appearances of contraction. The dullness on percussion of the contracting side is owing both to the falling inward of the thoracic parietes and to the absence of air in the compressed lung. The physical conditions of the lung and of the wall of the chest are much changed in this state of the disease; for both, especially the former, owing to the loss of their resiliency—the lung being constricted by false membranes, and compressed by the effusion, and thereby in great measure deprived of air; and the parietes of the thorax being insufficiently antagonized against the pressure from without by the much-diminished supply of air to the lung—are incapable of furnishing not only the usual sounds on percussion, but also the true indications of their existing states, unless by a strong pressure of the fingers, which are the media of percussion against the walls of the chest, and by varying the force, direction, &c., of the stroke.

84. Recovery from chronic pleurisy, with contraction of the chest, is more or less complete according to the reduction that has been made in the size and functions of the lung by the previous lesions. The recovery is rarely

so complete in persons advanced in life as in the young. In children, placed otherwise in favourable circumstances, and in young persons, recovery is often not only complete, but little or no inconvenience is caused by the contraction, which sometimes diminishes, especially in growing persons, owing to the increased development of the healthy lung. Some individuals, who have their sides contracted from the state of the disease, have continued to enjoy good health, and to pursue active occupations. LAENNEC has alluded to a distinguished surgeon in Paris who had his side remarkably contracted by pleurisy in his youth, and yet enjoyed excellent health, and was in the habit of lecturing twice a day without inconvenience. In most instances thus occurring in young subjects the contraction is not excessive, and the respiratory murmur is not altogether abolished. But in a greater number of cases, particularly those occurring in advanced life, contraction of the chest occasions such an habitual shortness of breath and tendency to palpitation as to incapacitate the subject of it from active exertion. Persons thus circumstanced also experience distressing dyspnoea, and otherwise suffer most severely from slight bronchial attacks, from catarrh, and febrile affections. Dr. WILLIAMS very justly remarks, that before the system becomes accommodated to the abridgment of respiration which this lesion produces, and even afterward, under unfavourable circumstances, there is an enfeebled or cachectic state of the whole frame, in which various trains of disorder may arise; and unless care be taken to counteract them by the means most favourable to the general health, scrofulous or dropsical disorders may be engendered, and develop new mischief in the respiratory organs or elsewhere. Although, therefore, contraction of the side of the chest may be viewed as a mode in which pleurisy may be cured, "it is one of the least favourable kind, and liable to many detracting circumstances."

85. *D. Empyema.*—In those cases in which the effusion is not removed by absorption, or in which the morbid secretion or effusion equals or preponderates over absorption, the accumulated fluid is productive of changes ultimately of a fatal tendency, if it be not evacuated either by a spontaneous perforation of the pleura, or by an operation. The persistence and character of the accumulated fluid are to be ascribed rather to the continued inflammation and change of structure of the pleura than to any other cause. The nature of the matter effused, its purulent character more especially, also favours the accumulation or impedes absorption. Something, also, may be imputed to a congested state of the lung, to tubercular infiltration, or to consolidation of its structure. When the circulation through the heart or blood-vessels is obstructed, the cause of increasing fluid accumulation is more manifest.

86. *a. The signs and symptoms of empyema* are nearly the same as those already described in connexion with very copious liquid effusion into the pleural cavity (§ 26, *et seq.*). In this, however, the more chronic state of disease, the accumulation of fluid, proceeding more slowly, generally is greater, and is attended by a more marked displacement of the walls of the chest, and of the viscera more immediately adjoining

them. Although the more urgent symptoms have in great measure subsided, particularly fever, dyspnoea, and pain, yet the enlargement of the side, and the displacement of the parietes, are often the more remarkable. The slow increase of the accumulation, the prolonged pressure, and, probably, as Dr. STOKES contends, the paralyzed state of the muscles bounding the effusion, favours the greater amount of fluid collection in this class of cases than in most others. The duration of the disease, the side which is affected (more frequently the left), the nature of the associations or complications, and the temperament and diathesis of the patient, modify both the extent and the phenomena of the accumulation, more especially the extent of enlargement of the side and visceral displacement. There is no certain indication usually furnished of the purulent nature of the fluid. When rigours or chills recur, with hectic, a soft, open pulse, perspirations, or even when these last are very prominent, there is great probability of the fluid being purulent; but these symptoms may be either but slight or nearly wanting. Protrusion of the intercostal muscles is considered by Dr. STOKES and Dr. H. ROE as more especially diagnostic of a purulent state of the secretion.

87. *b. When the fluid is purulent, ulceration and perforation* may ultimately attack the pleura at some point, and permit the fluid to be evacuated in a direction, according to the seat of the ulceration—either through the lungs, the walls of the chest, or the diaphragm; causing parts through which the evacuation takes place to be involved and more or less affected. Generally, the perforation of the pleura is consequent upon excavations in the layer of organized or semi-organized lymph coating this membrane; and sometimes death occurs before the perforation has become complete, or even proceeded farther than this false membrane. When, however, the pleura is perforated, the structures external to the ulcerated point in the pleura also become inflamed and ulcerated, and the accumulated matter makes its way in the direction of the ulceration, often burrowing between muscles or tendons, and even causing caries of the adjoining bones, as the vertebræ, ribs, or sternum.

88. LAENNEC and HASSE considered the perforation of the pulmonary pleura and discharge of the matter of empyema by the lungs and bronchi of more frequent occurrence than perforation of the walls of the chest. Dr. WILLIAMS doubts this, according to his own experience; and I think with good reason, as regards the whole parietes of the chest—costal and diaphragmatic. When the matter is discharged by ulceration through the lungs and bronchi, there is generally a violent fit of coughing, resembling or accompanied with vomiting, and attended by a copious expectoration or evacuation of it; the efforts, together with the quantity discharged, threatening suffocation; but remarkable alleviation of all the symptoms, and diminution of the evidence of dilatation and displacement, are the results. Dr. TOWNSEND describes the ulceration through the lungs and bronchi, in these cases, as being preceded by the formation of a gangrenous eschar, which is detached, the fistulous passage being lined with a false membrane, which prevents the matter

from infiltrating the substance of the lung, and conducts it to the air-tubes (*see* § 125).

89. When the ulceration of the pleura commences, and proceeds in a situation favouring the pointing of the matter externally, a soft fluctuating swelling is felt at some part of the chest; and it may generally be presumed to communicate with the pleural cavity by its becoming tender during expiration, and softer during inspiration, or by a sort of fluctuation caused by coughing. Dr. WILLIAMS remarks, what I have also seen in several instances, especially in children, that the matter not uncommonly burrows under and between the muscles and integuments of the chest, and points at several places, and at a distance from the perforation of the pleura. He has seen abscesses connected with empyema point in three cases under the pectoral muscle, once in the right hypochondriac region, and once close to the spine. That in the hypochondriac region had been mistaken for an abscess of the liver: in this case it was found, after death, that there were three perforations of both intercostal muscles and diaphragm; and between the layers of the latter the matter passed to the margins of the ribs, and there spread under the integuments, communicating with the other perforation between the ribs. In a case of empyema in the son of a medical friend, aged about six years, the matter was discharged near the margins of the right false ribs, and the boy recovered, and is now well, at the age of fifteen.

90. The superficial abscesses consequent upon perforation of the pleura are sometimes tender and painful; but they are occasionally also neither the one nor the other. They are generally slow in their progress to the formation of an external opening; usually spreading between the muscles and integuments, and causing a diffused or puffy tumour. When an opening is at last formed, there is a more or less copious discharge of matter, that recurs from time to time, especially during a forced expiration, or during coughing. "Sometimes air is drawn in through the orifice during full inspirations, and the next jets of matter issue with greater force, occasionally mixed with bubbles of air." After air is admitted into the diseased cavity, the pus, which was at first inodorous, generally becomes in a few days more and more fetid, and exhales the odour of sulphureted hydrogen. With this change in the discharge, or, rather, as a cause of this change, the constitutional symptoms assume an asthenic and irritative character. The pulse is much more accelerated; is quick and irritable; soft, open, and sharp; and the skin is alternately hot or burning, and bathed in a colluviate perspiration. The bowels become irritable; and general depression and asthenia, with irritative fever and rapid emaciation, soon carry off the patient.

91. The matter of empyema may be discharged by a fistulous opening, either uninterruptedly or at intervals, with more or less temporary relief. The recurring discharge may exist for weeks, often for months, and, in rarer instances, even for years; the patient occasionally recovering, but much more frequently sinking from the extent and nature of the disease. Recovery is oftener seen in the young than in persons even moderately far advanced in life and

when it is likely to take place, the discharge soon becomes less, and either does not present, or loses, its fetid character. The external opening closes, and the side becomes contracted, as already described (§ 78, *et seq.*), respiration partially returning in some portions of the chest.

92. *D. The terminations of chronic pleurisy* may be readily conceived from what has been already stated. The *duration* of this state of the disease varies from six weeks to a year, or even much more, when it terminates either in *recovery* or in *death*.—(a) *Recovery* often takes place after a gradual *absorption* of the effused fluid and of the albuminous exudations, or after the organization of the latter into false membranes. This mode of termination is evinced by the signs mentioned above, and by the depression and contraction of the affected side (§ 78).—(b) *Recovery* much more rarely occurs by the evacuation of the accumulated fluid through a *perforation of the pleura*, and a fistulous opening, either in the lungs and bronchi, or in the thoracic parietes (§ 88).—(c) *Death* is frequently caused, 1st. By the general exhaustion and hectic attending the disease, especially when the accumulated fluid is puriform, or when the substance of the lungs is consolidated or tuberculous; in these cases the patient sinks in the same manner as in tubercular consumption; 2d. By the sudden asphyxia of the patient: in these, sudden attacks of dyspnoea, almost amounting to suffocation, sometimes are complained of, at intervals, before the fatal seizure; these attacks often occur during the night, and may return almost nightly. Death may take place very nearly as suddenly as from disease of the heart, and may be thus mistaken for death from this cause, if the history of the disease be not known or ascertained.

93. III. COMPLICATIONS OF PLEURISY.—*Pleurisy*, in either of the states described above, is very frequently a *primary* and *simple* disease. But it is also often *associated* with inflammation of an adjoining tissue or organ, or with some other lesion or malady. In this *complicated state*, it may be either the *primary* or the *secondary* disease; the exact condition and succession being of importance in respect both of the prognosis and of the treatment. I will, therefore, notice some of the more frequent complications of it observed in practice; and, in some instances, a mere notice is all that is necessary, as the suggestion of the associations which the disease so often presents will put the physician on his guard, when he will not fail of detecting it.—a. *Pleurisy* in any form, but more especially in the acute, is often associated with *inflammation of the substance of the lung*, forming *pleuro-pneumonia*, described in the article LUNGS (§ 73-75), or *pleuro-pneumonitis*, *peripneumonia*, or *peripneumony*, of various writers. It is unnecessary for me to notice this complication farther at this place, than to add that the inflammation, in these cases, most commonly assumes a sthenic character, although the asthenic state is occasionally also met with; and that, although both diseases, or, rather, the inflammation of the two different structures, may be coetaneous as well as coexistent, yet the pleuritic is more frequently consecutive of the pulmonic affection than the pulmonic is of the pleuritic. This may be owing, in great part, to

the nature of the tissues, and of the connexion existing between them; but it is more probably owing to the general tendency of inflammations of parenchymatous organs to extend to the periphery.

94. *b.* Pleurisy, either in a simple form, or associated with pneumonia or with bronchitis, is one of the most important complications of *exanthematous* and *continued fevers*. When it is the complication or associated local affection in these constitutional maladies, it is always acute, unless when it appears in the course of convalescence from either of them; and it presents the same characters or diathesis, in respect of vascular action and vital power, as these possess; but the *asthenie*, in its various grades, is the most common, especially if it supervene at an advanced period of the fever, when the vital energy is depressed or exhausted, and when the circulating fluids are morbid or contaminated. Whenever the breathing is very short and frequent, with or without cough or pain in the side or chest, in these diseases, then this complication should be suspected, and a careful examination be immediately instituted, as the progress of the local mischief is generally rapid when it occurs in the course either of these or other constitutional maladies.

95. *c.* Pleurisy, generally of an adhesive form, and of chronic duration, very frequently accompanies *tubercular consumption* and chronic *tubercular pneumonia*. This pleurisy is generally the consequence of the irritation or chronic inflammatory action occasioned by the tubercular deposits in the lungs, especially when these exist near the surface, or when the tubercles soften in that situation, and are followed by cavities. In these cases the pulmonary pleura becomes implicated in the inflammatory action in the immediate vicinity, throws out lymph on its free surface, which excites a corresponding morbid action in the opposite part of the costal pleura, and forms close and firm adhesions between the lung and walls of the chest. This state of chronic or subacute pleurisy is most frequently observed near the summits of the lungs or upper regions of the thorax; is most commonly attended by adhesions, without fluid effusion; or, if such effusion occur, it is soon absorbed (*see* § 120). In some cases, however, tubercles soften and cavities form near the surface of the lung, and perforate the pulmonary pleura at the nearest point to them, without giving rise to adhesion to the opposite surface. In these, fluid effusion often takes place before the perforation is completed, and air passes into the pleural cavity, giving rise to the lesion denominated *pneumothorax*, which is fully considered in another place. The association of pleurisy with tubercular consumption is more fully considered in the article on this latter malady.

96. *d.* Pleurisy is sometimes complicated with *pericarditis*. Generally the pericarditis is of the dry form, in which it has been remarked in several instances by Dr. STOKES. In two cases, to which I was called shortly before death, the previous history of which was not precise, but which were considered and treated as very acute cases of pleuro-pneumonia, the *post-mortem* examination disclosed the association of pleurisy with pneumonia and pericarditis. In both these cases there were considerable effu-

sion, with shreds and pieces of lymph, into the left pleural cavity and pericardium, the diaphragmatic pleura being much affected. Dr. STOKES remarks, that where the pericarditis is of the dry form, the symptoms are not so violent as in that with effusion. He has observed this complication in cases of acute pleuritis, and in two instances of very chronic empyema. In the latter cases, the usual symptoms of pericarditis were altogether wanting, and no new suffering marked the invasion of the disease, which was discovered only by auscultation. The observations of M. BROUSSAIS apply chiefly to cases of this complication, with copious effusion into the pericardium, in which there are generally pains in the præcordia, with great anxiety and want of sleep. The patient sits bending forward, with his head resting on his knees; and yet, notwithstanding great concentration of the pulse, there is a tendency to fainting, and almost complete absence of fever. (*Traité des Phlegmasiæ Chroniques*, t. i.)

97. *e.* Although pleurisy is more frequently caused by, than associated with, acute rheumatism, still this complication is occasionally observed, the still farther complication with endocarditis or pericarditis being also met with in rare instances. This very complicated state of disease has been seen by me in children between eight and thirteen years of age, in three cases, in all of which it was recognised during life, and ascertained by inspection after death.

98. *f.* The complication of *hepatitis*, especially of inflammation of the convex surface of the liver, with pleurisy, is by no means infrequent, and supervenes chiefly in the course of the acute form of hepatitis. It occurs also in the chronic form, especially when an abscess of the liver is passing through the diaphragm, either into the pleural cavity, or into the lungs and bronchi, adhesions having been formed between the opposite surfaces of the pleura. This form of the complication is noticed in the article on the diseases of the LIVER (§ 141–145); but I have seen cases of chronic hepatitis, not connected with abscess, that have been associated with empyema of the left side, the heart being pushed over towards the right side. I am at this time attending a female in Brook-street, aged between thirty and forty, who, according to the history of the case furnished me, appears to have been attacked by subacute hepatitis, attended by suppression of the menses, and followed by ascites, and by chronic pleurisy of the left side, with effusion, displacement of the heart, and dilatation of the thoracic parietes. I was recently requested, by Mr. SIMS, a surgeon who had practiced in India during many years, to see a lady, aged about fifty, who was the subject of a most acute attack of hepatitis, to which rapidly succeeded dry pleuritis and pneumonia of the right side. In this very remarkable case, the symptoms and signs of hepatitis, of diaphragmitis, of diaphragmatic pleurisy, and of pneumonia with rusty expectorations, were distinctly recognised by Mr. SIMS and myself. The patient recovered, and is now quite well.

99. *g.* Pleurisy may also be consecutive of, and complicated with, *peritonitis*, especially partial peritonitis of either of the superior abdominal regions. I have seen several instances of acute asthenic pleurisy, with abundant

sero-albuminous or sero-sanguineous effusion, complicating the several varieties of puerperal fever, and puerperal peritonitis and phlebitis; but in these complications the pleurisy was generally latent, death having taken place before obvious dilatation of the side or displacement of organs occurred. Indeed, in most of these cases, the pleuritic complication was double, although the fluid effusion and other lesions were much greater in one side than in the other, the amount of effusion in either side not being so great as to compress the lung in a remarkable manner.

100. I was lately called to a gentleman who had just arrived from the Azores with ascites, consequent upon repeated attacks of *peritonitis*; pleurisy, with effusion, having also supervened, and proved the more immediate cause of death. Upon examination, the appearances described in the article *PERITONEUM* (§ 88, *et seq.*) were found, the adhesions being numerous, very long and thick, and the serous effusion very abundant. Some of these adhesions were round, as large as the first or second finger, with serous or polished surfaces, and formed cylinders, the external layers of which were organized and dense, and two or three lines in thickness, the interiors being loose and cellular, yet containing very much fatty matter, or, rather, consisting almost entirely of adipose tissue. A turbid serum was found in considerable quantity in the left thoracic cavity, in smaller quantity in the right, and adhesions, cylindrical or nearly so, stretched through the effused fluid, from the pulmonary to the diaphragmatic and costal pleura, in several places, and presented similar appearances to those in the peritoneal cavity; the thicker and the more cylindrical adhesions having organized serous surfaces, and cellulo-adipose centres; but the adipose matter was not so abundant in them as in the peritoneal adhesions.

101. *h.* In most of the complications above mentioned, the pleuritic inflammation is secondary, or consecutive of that with which it is complicated, unless in some cases of pericarditis. But in the course of many cases of chronic pleurisy, or empyema, complications may occur, and render still more dangerous, or even fatal, this already dangerous disease. This is more particularly the case when the fluid accumulation in the pleural cavity is of a purulent kind. In these, especially, various alterations take place in the surrounding structures, caused both by the nature of the accumulated fluid and by the mechanical influence of it. The substance of the lungs, the bronchi, the pericardium, and the mediastinum are either more or less implicated by the early stages of the pleuritic inflammation, or are consecutively irritated, inflamed, or otherwise changed by the nature and quantity of the effusion. Consolidation or atrophy of the lung often results; chronic pericarditis, with adhesions to the heart, sometimes takes place; the bronchi undergo various changes, and are often inflamed; the vessels of the lungs are altered, pulmonary phlebitis even occasionally supervening; and the vertebrae, or even the ribs, sometimes becoming carious. In addition to these effects, the actions of the heart and large vessels are impeded or disordered; while the blood becomes morbid, owing to the greatly impaired

function of the lungs, and all the vital actions consequently languish.

102. IV. *PLEURISY IN THE DARK RACES.*—Pleurisy is very often met with in the negro and other dark races, particularly when they pass into high latitudes and cold regions; and in these circumstances it is very frequently associated with pneumonia, tubercular consumption, bronchitis, &c. *Acute pleurisy* in these races is frequently latent, most commonly presents asthenic characters, and is generally attended by copious serous, sero-sanguineous, or puriform effusion. Hence, unless the shortness of breathing, acceleration of pulse, short cough, and debility, with rapid exhaustion after slight exertion, usually attending the early stages of the disease in these varieties of the species, attract due attention, acute pleurisy will rapidly pass to its ultimate period, or may terminate fatally before its existence is ascertained. *Chronic pleurisy* is also frequent in these races, especially when they migrate to colder than their native climates. It often then assumes the purulent form, and is generally complicated with pulmonary tubercles. Pleurisy, both in acute and chronic states, frequently with effusion in the former state, and often with adhesions in the latter, is not an unusual complication of pulmonary tubercles in the dark races, especially after change of climate and exposure to cold, and is very commonly either latent or masked by the symptoms caused by the bronchitic complication, which is also frequently present.

103. V. *PLEURISY IN INFANTS AND CHILDREN.*—Pleurisy is met with in children of all ages; but it is most frequently seen, especially in an uncomplicated form, in children upward of five years of age. Before that epoch, it is rarely unassociated with pneumonia, and even, also, with bronchitis, pleuro-pneumonia being the most common state of disease. In children, as well as in adults, pleurisy is much more frequent in male than in female children. In this class of subjects it is frequently consecutive of pneumonia, and of eruptive fevers, either as a complication of those fevers, or as a sequela of them during some period of convalescence. Indeed, there is a remarkable disposition to the supervention of pleurisy, or of pleuro-pneumonia, during the whole period of convalescence from these fevers, more especially until the healthy functions of the skin are entirely restored. In other respects the causes of the disease in children are the same as those of adults; but, as shown when remarking on the prevalence of pneumonia in children (*see LUNGS, Inflammations of*, § 122, *et seq.*), these causes act more injuriously, and their effects, whether in the form of pneumonia, of pleurisy, or of pleuro-pneumonia, are the more to be dreaded the younger the child which becomes the subject of them.

34. Pleurisy in children is most frequently single, as in adults. MM. RILLIET and BARTHEZ state that, in the uncomplicated state, pleurisy is somewhat more frequent in the right than in the left side, while the complicated states occur more frequently in the left. This, however, does not agree with my experience; as I have found, in children as well as in adults, pleurisy in every form more frequent in the left than in the right side of the chest. As to

the products of inflammation of the pleura, false membranes, and serum more or less turbid, are most commonly observed in this class of patients, and the false membranes are most extensive and most generally found in the pulmonary pleura, and least abundant and frequent on the diaphragmatic pleura.

105. The accession of pleurisy is not always attended by rigours or chills, especially in young children—never in infants; and the *decubitus* in them especially is not much different from the usual. Sometimes *decubitus* on the back, with the shoulders raised, is preferred. In young children and infants especially, when associated with pneumonia, as pleurisy usually is, little or no fluid accumulates in the pleural cavity, although lymph is thrown out. The infant is restless, cries constantly, especially when moved or held erect; the skin is hot and dry; and the rubbing or creaking sound is heard on auscultation, the respiratory movements of the affected side being diminished. During the acute or early stage of the disease, in older children effusion, although abundant, seldom causes dilatation of the side: this symptom is rarely observed until the disease has become chronic, and then it is often remarkable and attended by pallor, enervation, debility, night perspirations, and loss of appetite. If the fluid be not absorbed or evacuated by an operation, death ensues, after one, two, or more months, the patient being in a state of complete marasmus. In the case of a young relative of my own, pleurisy, followed by empyema of the right side, occurred at the age of eight years, and the matter was evacuated externally by a fistulous opening, as described above (§ 99). He perfectly recovered; and the functions of the lung and the size of the side are now natural.

106. The complications of pleurisy are most to be dreaded in children; more especially when pleurisy occurs in the course of eruptive fevers, or of pneumonia or hooping-cough. In very young children, and in infants, this disease, whether simple or complicated, and more particularly when associated with pneumonia or bronchitis, or when developed in the course of hooping-cough, is very frequently fatal; and in infants it may terminate fatally, by causing suffocation in twenty-four hours. In older children, especially when uncomplicated, pleurisy, even in the more acute forms, is much more disposed to assume a chronic form than in the very young, in whom the more prolonged states of the disease are rarely seen.

107. VI. THE STATE OF THE BLOOD IN PLEURISY has recently received attention, but more as regards its chemical constitution than as respects its sensible appearances. Formerly, and with much better reason, these appearances attracted the chief, and indeed no small attention; for they furnish very important information as to the states of vital power and of vascular action characterizing the disease at the time when the blood is abstracted; and they moreover aid the physician in forming his diagnosis—still more in giving his prognosis—but most of all in determining his indications of cure, and in selecting the means of fulfilling them. Yet this important source of information is neglected, and the particular mode of studying the conditions of the blood in disease that actually furnishes the smallest amount of

useful information to the practical physician is that which now attracts attention, although this very small amount cannot possibly be ascertained by the practitioner at the only time when it can prove in any way advantageous, while it causes the neglect of that knowledge which instantly furnishes the most important pathological and therapeutical indications.

108. A. The appearances of the blood, especially of the coagulum, vary remarkably in pleurisy, according to the states of vital power and vascular action.—a. In the *sthenic acute form* of the disease, the blood taken from a vein generally presents the buffy coat and a firm coagulum, the quantity of fibrin being generally about double the proportion observed in health. If the first bleeding has been early in the disease, the blood will generally present a firm and rather large coagulum, but frequently be neither cupped nor buffed, or but slightly so, although a second venesection, performed only a few hours afterward, will present these appearances in a high degree, a third depletion also presenting them, but in slighter grades. However, nothing can with certainty be affirmed as to the effects of a second or third depletion, as much will depend upon the quantity of blood taken away relatively to vascular fulness and action, and to the powers of the constitution; but commonly the proportion of the coagulum to the serum, or of blood-corpuscles becomes diminished, while the fibrin may be increased in the second blood-letting, but diminished in a third and fourth. In these cases, as well as in pneumonia and acute rheumatism, the quantity of fibrin is generally great in proportion to the degree of fever, pain, and sthenic action, while the blood-corpuscles, or hæmato-globulin, is diminished with the quantity of blood taken away. In fat persons, especially, the serum often assumes a whitish or milky hue after repeated venesection, owing to the fat absorbed and conveyed into the blood. (See art. Blood, § 84, 96–108.)

109. b. In the *asthenic, cachectic, and latent states*, as well as in most instances of chronic pleurisy, the appearances of the blood are still more various than in the sthenic form; but in many instances they furnish important indications of cure. When vital depression is very remarkable, and vascular tone impaired or exhausted, the coagulum is either soft or the blood coagulates imperfectly, although the quantity of fibrin may be greater than in health; and a large soft coagulum is often imperfectly separated from the serum. In many of these cases the blood presents much of the appearance described in the article BLOOD (§ 94); but I have so rarely seen blood taken from a vein in these states of the disease, that I am unable to add more from my own observation, as to the appearances of the blood in these circumstances.

110. B. *Analyses* of the blood in pleurisy have been made by ANDRAL and GAVARRET, who found that the quantity of fibrin was increased to very much more than double the natural quantity; and that the increase was greatest in the most acute and most febrile and painful cases, and was the least in the chronic and non-febrile. BEQUEREL and RODIER analyzed the blood of five men attacked with acute pleurisy, and found the fibrin much more than double the healthy proportion, while the albumen and

blood-corpuscles were somewhat diminished; but the results of the observations of the physicians above mentioned are in no way precise, nor are the changes very remarkable, excepting only as respects the quantity of fibrin; the proportions of the several constituents of the blood depending much upon habit of body, sex, and constitution of the patient; upon the state, grade, and form of the disease; upon the states of febrile action and vital power; upon the stage of the malady, and the quantity of blood previously abstracted. Let the candid and practical reader peruse the accounts of numerous analysis of the blood made by German and French chemists and pathologists, especially those made with a view of showing the composition of it in pneumonia, pleurisy, rheumatism, erysipelas, &c., and he will find, according to the summaries of these analyses given in SIMON'S Animal Chemistry applied to Physiology and Pathology, with the additions by Dr. DAY, the very slight differences, or even the sameness, of the results, as regards these and some other diseases. Having obtained the full amount of knowledge he possibly can derive from these sources, let him next endeavour to apply it to practical purposes; and if he can do so, with only one tenth of the advantage which may be derived from attention paid to, and an acquaintance with, the sensible appearances and properties of the blood, he will be much more fortunate than I can credit.

111. It is very justly remarked by VOGEL, that it is very difficult—indeed impossible—to draw any certain conclusions from the statements of the above-mentioned and other observers, respecting the changes of the several constituents of the blood, or the causes of these changes. In fact, our whole knowledge of the chemical constitution of the blood in both health and disease is most unsatisfactory, and the statements of different writers vary so widely, that it is impossible to deduce any general laws from them. And I may add to this opinion of this able pathologist, that writers on the chemical constitution of the blood in disease have shown only how very little information they were able to give upon the subject; and that little evinces its insufficiency even for the purposes of either a theory or a hypothesis, and its almost total inapplicability to any practical purpose. It is, therefore, to the old fashion of observing the sensible changes and states of the blood, and of connecting these changes with the states of vital power and of vascular action upon which they manifestly depend, that we must recur with any hopes, in the present state of our knowledge, of practical advantage.

112. VII. THE PATHOLOGICAL ANATOMY OF PLEURISY.—A. The earliest appearances of inflammation of the pleura are similar to those which I have described as being observed in inflammation of the PERITONEUM (§ 81, *et seq.*), and consist of a congested state of the capillaries, which are congregated, here and there, beneath the still transparent membrane. The red colour produced by these vessels at certain points, deepens and becomes more diffused. These points are somewhat prominent, and, although scattered and distinct at first, they soon enlarge and coalesce. Patches and streaks are also observed, either darker than the rest, resembling small ecchymoses, or of a pale red

hue, as if from imbibition. The pleura now becomes dull, and loses its polish and smoothness. The redness spreads and becomes more and more uniform. Soon afterward the rudiments of adventitious membrane may be perceived. The spots originally reddened by repletion of the capillaries present little, dull, whitish or yellowish points, which rise above the surface in the form of flat granules, and ultimately coalesce. The pleura, as HENLÉ has shown, consists of several layers of superimposed cellular tissue, more and more closely attached to each other, the free surface being a thin layer of epithelium cells. Blood-vessels penetrate all these layers, excepting the exceedingly delicate epithelium membrane formed by these cells. The inflammation, therefore, is not seated, or does not commence, in the epithelium membrane, but in the subjacent cellular layers, this epithelium being thrown off at an early period of the disease. While these changes are proceeding in the pleura, the layers of cellular tissue connecting the pleura to the subjacent parts are more than usually vascular, and are more or less infiltrated with a yellowish, semi-gelatinous fluid; but this implication of the external cellular tissue is only occasional, or exists chiefly at the commencement, and is removed as effusion or other advanced changes take place. In rare instances only are alterations of the pleura and of the subjacent cellular structure observed to proceed, *pari passu*, with each other, more particularly as regards the costal pleura.

113. Consequent upon the changes now described, especially upon the grayish or yellowish points mentioned above, which are the initial and expanding rudiments of the consistent or membranous effusion, a slight, sometimes a much more abundant exudation of serum is also observed. When the progress of the inflammation is soon arrested these products are inconsiderable; but more frequently, and when the disease proceeds but little farther, the pleura is found as far as the inflammatory injection extends, to be lined by a very thin layer of plastic exudation, forming a delicate membrane, mostly opaque, which veils the inflammatory redness underneath it. The liquid effusion contained in the pleural cavity consists of a small quantity of a yellowish limpid fluid, or of a more abundant collection of a turbid, or of a reddish or mahogany-coloured serum, containing delicate flocculi. HASSE supposes that upon the condition of the thin adventitious membrane covering the pleura depends the length of time requisite for the absorption of the fluid; and that the more heterogeneous the quality of the former, the greater will be the impediment to the absorbents acting upon the latter. However, there are other circumstances besides the state of this membrane, which will either impede or accelerate absorption of the contained fluid, and it can hardly oppose any great obstacle, as it either enters into organic union with the serous tissue, or else it is gradually dissolved in the fluid.

114. When the inflammation either continues unabated, or steadily, and gradually, or more or less rapidly increases, the morbid products accumulate in proportion, exhibiting at the same time the most manifold differences. These differences depend more or less upon

iathesis or peculiarity of constitution and emperament, upon the grade of inflammation, upon its character and the degree of tone or of vital power attending it, and upon the state of the blood itself. The German and French pathologists, more especially HASSE and ANDRAL, while they describe these differences with much precision, take insufficient note of the several pathogenic conditions upon which they certainly depend more or less; although it is very difficult to assign these differences or states of the inflammatory products in this disease to any one or more states of the system or of the circulating fluids, inasmuch as these products evidently undergo various changes after their accumulation and during their retention, and, moreover, the states of vital power, of inflammatory action, and of the blood attending their exudation and collection, soon change and become very different when they are retained for some time, these states being rather the consequences of the accumulation and retention of these products, and of the changes these products have undergone, than the causes of the differences or peculiarities they present when they become the objects of examination. To say, therefore, that variety of character in the products of inflammation of the pleura "is entirely founded on individuality," as some pathologists have contended, is to confess ignorance under the mask of a term. That the varieties observed are chiefly to be referred to the states just enumerated will be confirmed by more close and precise observation, although the difficulties of ascertaining the dependance of certain alterations upon determinate states of vital action, while the products of these states cannot be immediately examined, I am still disposed to believe. The exact appropriation of the several varieties of these products to the pathogenic states which produce them can hardly be expected, seeing that both the causes and the effects are the subjects of continual change; but an approach to it may be made sufficiently close for all practical and useful purposes.

115. *a.* The product of pleurisy, most simple, and most frequently observed, is a transparent yellowish jelly or lymph, and which is effused with great rapidity and in considerable quantity when the inflammation is intense. It is partly diffused in layers between the pulmonary and costal pleura, and partly subsides to the lowest part of the pleural sac in pellets or flakes surrounded by a small portion of fluid. This gelatinous exudation or lymph consists almost exclusively, and often in nearly equal proportion, of the fibrin and serum of the blood, the latter most frequently predominating, with a very little colouring matter, attracted here and there to the inflamed surface. It is *susceptible of organization throughout*, and blood-vessels form in it with surprising rapidity. HASSE met with a case in which pleuritic pains occurred twenty hours before death, and found, at the corresponding part, this gelatinous lymph, in which delicate vessels were observed shooting from the borders. This product soon adheres to the surfaces of the pleura where they approach each other, and a very few days suffice to produce an extensive cohesion between the two. The rapid growth of vessels gradually confirms the union, and the aqueous

portions of the effusion soon being absorbed, the formerly separate surfaces now adhere by means of a soft vascular and cellular layer or false membrane. The disease often terminates thus favourably, without the function of the affected part being materially or permanently disturbed. But the inflammation, having given rise to these changes, either partially or fully, and being nearly extinguished, may be rekindled, and the incipient adhesions may be stretched, or torn away, or even dissolved by the fluid poured out during the consecutive attack, and various other changes produced in the products previously formed, as well as other more novel deposits may take place.

116. *b.* The pleuritic exudation or lymph is not always of this organizable kind, or so german to the organism, owing to a depraved habit of body, to the state of vital power, and most probably, also, to the condition of the blood. Without, however, ascribing the difference to these states, Professor HASSE believes that ingredients very often enter into the composition of the pleuritic effusion which, either from too early consolidation, or, from some peculiarity of character, render it less susceptible of consolidation. These substances he considers as being far less easy of assimilation, and, acting as foreign bodies, serve to embarrass the surrounding parts. Adventitious membranes of this kind, and which are only *conditionally susceptible of organization*, appear not to form so rapidly as those just described. They generally consist of several either homogeneous, or else distinctly different layers, largely investing and firmly adhering to the pleura. Their consistence resembles that of a hard-boiled white of egg. They tear easily, and present, when torn, a fibrous-like texture. The colour of these plastic or albuminous masses is mostly of a yellowish or dull white; but they occasionally vary greatly, passing to a faint red, or into a violet or mahogany tint. The tinge is sometimes equable, but is also occasionally irregular, or patched, or streaked, or different in the layers or surfaces. These membranes are always opaque; their free surface is usually paler and softer than that adhering to the pleura, and is usually villous or reticulated. The cavity of the pleura contains, in addition to this false membrane, a considerable quantity of a slightly turbid or flocculent fluid, or a light-brown or reddish liquid, bearing some relation to the quantity and character of the false membrane. When there is a more complete development of blood-vessels in this membrane, there is also a smaller amount of fluid; and where, on the other hand, the organization of the membrane is imperfect or arrested, or when the consistent product is merely that of an unorganized coagulum, the fluid effusion is relatively more abundant, and, as HASSE supposes, with great probability, much less likely to be absorbed. It is not unlikely that exudations of the latter kind are liable to various changes during their retention, causing farther alterations in both the more consistent and more fluid parts, preventing or retarding the organization of the false membrane, and the absorption of the liquid. In these cases the disease is prolonged, and does not terminate favourably until the adventitious membrane has become organized and the fluid ab-

sorbed. But in those cases in which these results do not take place, the constitutional efforts caused by the morbid products, and the vital efforts made to resist the extension of the changes which these products occasion, produce a febrile or hectic state of the frame, which acts upon the local lesions, and these again react upon the constitutional disturbance until the vital functions are at last arrested. When the effused matters are much altered during retention, or assume a more morbid or irritating quality, even the partial absorption of them causes hectic of a more or less acute or rapid kind. Absorption of such matters is so constantly attended by hectic and emaciation, that Dr. HODGKIN, with much reason, regards the absence of these symptoms as evidence of its non-existence. It often does not proceed steadily, but remains stationary, until some intercurrent disease, in no way connected with the pleuritic malady, accelerates its progress.

117. c. When plastic matter or albuminous lymph is exuded in a very short period, by the intensity of the inflammation, *it does not enter into organic union* with this membrane, with which it is only loosely agglutinated, owing either to its rapid coagulation, or to the constitution of the exudation, or to the state of vascular action in the pleura. The coagulum then generally assumes the form of a honey-combed false membrane, or it presents imbricated layers; or it merely consists of irregular flocculent layers, whence scattered filaments run across the cavity of the pleura, while others shoot from the free surface, and give an irregular villous appearance to this surface. These plastic exudations are generally soft, opaque, and of a pale yellow hue. Along with the matter forming these depositions, a considerable quantity of liquid is also effused, which is sometimes tinged with the colouring matter of the blood, imparting in such cases its tinge to the whole morbid product. The more solid part of the exudation surrounds the more liquid portion, and forms an envelope for that portion; and being unorganized, and interposed between the fluid part and the pleura, prevents the absorption of that part. In these circumstances the disease becomes chronic, if death does not soon ensue, or assumes the form of *empyema*.

118. d. The *purulent* or *empyemic* form of effusion may be the result, as HASSE observes, either of a high degree of inflammation at the outset, or of the introduction of external air reacting on the inflamed serous surface and its product, during the progress of the disease. But may it not also arise from consecutive changes in the vascular action of the inflamed membrane, and in the effused fluid independently of the admission of the external air? I believe this to be the case in some instances. Suppuration of the pleura, however, is most marked where *pneumothorax*, with violent inflammation, follows the bursting of an abscess, or of a tubercular cavity into the pleural cavity. (See art. PNEUMOTHORAX.) In this case the pleura soon becomes dull and of a dingy gray, and secretes a thick tenacious, puriform fluid, covering the surface of the membrane, and collecting in the most depending portion of the cavity. In some instances a pure liquid pus is very abundantly formed, and

is often mingled in various proportions with coagulable substances, especially with a very soft, thin, puriform, false membrane, which are either deposited upon or slightly adhere to the pleura, or which are mingled with the purulent fluid, in the form of pellets or flakes. Unless the pus find a ready outlet, or become sequestered within false membranes, this state of the disease soon terminates fatally.

119. e. Owing to the circumstance of the pleura being inflamed in different degrees, in different portions, or to the occurrence of a succession of attacks, or to the recrudescence of a subsiding inflammation, *several of the kinds of morbid product* above described are often met with in the same case. The most various combinations both of consistent exudation, organized, organizable, and unorganizable, and of liquid effusion, are thus sometimes seen in the same subject. HASSE justly remarks that pus, at whatever period it may be generated, stamps all other substances effused with its own impress. Plastic organizable exudations are thus liquefied and converted into pus; that which is coagulated turns yellow, becomes putrescent and flocculent, and, in like manner, resolves itself, partially at least, into pus. This statement, in fact, confirms the view which I have entertained above (§ 73) of the not infrequent conversion of other and more chronic states of pleurisy into that of a purulent or empyemic form, independently of the admission of the external air.

120. f. The *tubercular form* presented by the pleuritic products is one of the most important, and occurs chiefly in the scrofulous diathesis, and when tubercles at some one period of their development exist in other organs, especially in the lungs. As the tubercular constitution changes the plastic products of nutrition in particular structures, even in the circumstances of ordinary health, or causes the cytoblastemata of tubercle to be secreted conjointly with normal elements in these structures, so does it exert the same influence in the formative processes consequent upon inflammatory action. When pleurisy occurs in this constitution, and gives rise to the organizable or first form of product described (§ 115), there are seen, either simultaneously with the incipient formation of vessels, or earlier, dull points as large as pins' heads, scattered through the gelatinous effusion; and these points ere long change into granules. In the second form of false membrane (§ 116), tubercles likewise often appear in the shape of white, flat granules, distinct both in colour and consistency from the rest of the mass. These granules are inaccessible to the vascularity which soon pervades the organizable product. Professor HASSE remarks the existence of these granules, even the plastic substances deposited from purulent effusion, but he has never met with them in the adventitious deposits which are not susceptible of organization (§ 117). In pleurisy, as well as in other diseases, the characteristic influence of tubercles is exerted; for, by acting as substances alien to the organization, they keep up irritation, and the continued secretion of fluid and consistent matters; and they impede or frustrate the function of absorption. A portion, also, of these effects may be imputed to this particular diathesis, and to the circum-

stance of tubercles in various stages of growth being generally also present in other organs, more particularly in the lungs.

121. *g.* The *sanguineous state* of the products of pleurisy was particularly noticed by LAENNEC. The various grades of reddish colour imparted to pleuritic exudations by the colouring matter of the blood have already been slightly mentioned. Sanguineous coloration of the fluid effused is most frequent in the tubercular states of pleurisy. It is only in rare instances that the blood itself exudes into the pleural cavity in this disease; and when this occurrence takes place, little clots are found at the bottom of the collected serum, or deposited between false membranes. Instances of the entire effusion, consisting of pure blood, are mentioned by ANDRAL and HASSE; but these should be referred rather to hemorrhage into the pleural cavity than to inflammation of the pleura. Even when blood is effused into this cavity it will necessarily produce inflammation; and hence, in cases where pure blood, or clots of blood, are found in this cavity in connexion with inflammatory products, it may be difficult to determine that these are not the products of an inflammation excited by a primary hemorrhage into the pleural sac, effused blood generally causing inflammatory action in the tissues surrounding it.

122. *h.* The spontaneous evolution of a *gaseous fluid* from the products of pleurisy has been believed in by some pathologists, and denied by others. The question at issue is, whether or not these products may become so decomposed during the life of the patient as to form a gaseous fluid. We know that this effect is not unfrequently observed after death. Dr. HODGKIN doubts the possibility of it during life, and ANDRAL and HASSE appear very nearly to agree with him; for, in instances which occurred to them, in which gas seemed to have been spontaneously evolved from these products, they admit the possibility of some perforation of the pleura to have existed, although they failed to detect it. Although the exuded matters, fluid as well as more consistent, may long remain either unchanged, or but slightly changed, as long as the vital energies are not very much impaired, yet when these energies are very far reduced, the products of inflammatory action are either insufficiently, or no longer controlled by them, and various changes must ensue. Some of those changes may be ascribed to endosmosis and exosmosis; others to the states of vascular action and of absorption; and a portion even to incipient putrefaction; but death usually occurs before this last proceeds far. The ulterior changes of the more fluid matters effused in pleurisy are as yet not fully ascertained, especially with reference to the different grades of vital power; and the question as to the spontaneous evolution of gas from these matters, in the most unfavourable circumstances of the disease, and when vital power is remarkably reduced, still remains undecided.

123. *i.* The most important change that takes place in the gelatinous and more consistent products of pleurisy is their *vascular organization*. This process has been explained in two ways. DÖLLINGER and others have supposed that the exudation, possessing a derived grade

of vitality from the surface producing it, has hence the power of producing a movement of its molecules, of transforming these into blood-globules, and of developing canals for their circulation independently of any connexion with the blood-vessels of the surrounding tissues, the circulation in the false membrane becoming connected with and subject to that in these tissues only subsequently, and by slow degrees. This theory has not been supported by accurate and direct observation, and it has only the remote and loose analogy of the incubation of the egg to support it: a process which possesses elements entirely wanting in the organization under consideration. The other explanation is more obvious, and admits of visual demonstration. It has been observed by HASSE, KIERNAN, HODGKIN, myself, and others, in various stages of its progress; and it may be briefly stated, that, wherever vessels had formed in adventitious membrane, they proved to be continuations of the branches ramifying in the serous coat, having penetrated the false membrane at numerous points, and then branched out in a stellate manner, or having formed into partly divergent, partly parallel, fascicular groups. In those false membranes which are less organizable, or only conditionally so (§ 116), the descriptions of LAENNEC, FORBES, and GENDRIN show that a multitude of little red elevations appear on the serous membrane, like clusters of protruding vessels. These elevations impress corresponding pits in the adhering surface of the false membrane, and upon the surfaces of these pits appear little arborescent or stellate extravasations of blood. By degrees these arborescent extravasations become more strongly marked, and assume the appearance of vascular ramifications. LAENNEC states that these ramifications present an outer and softer layer, formed by desiccated blood; and that this layer encloses a small whitish chord of coagulated fibrin, apparently hollow in the centre, and pervious to the blood stream. These thick-walled canals gradually change into the natural coats of the vessels, which, pursuing their course, thus seek to traverse all the organizable portions of the false membrane. Professor HASSE remarks, that some plastic substances are possessed of so little power of attraction over the capillary vessels of the inflamed pleura as neither to form these little vascular prominences, nor to occasion the little stellated extravasations on the new membrane. These heterogeneous formations go on irritating the pleura until another false membrane is thrown out, which, acting as an intermediate vascular link, establishes something approaching to vegetative reciprocity between the two; and, being itself devoid of nerves, obviates morbid irritation.

124. *k.* Whatever does not sooner or later become assimilated or organized; whatever is not converted into vascular cellular tissue, or is not removed by absorption, remains perfectly isolated and encysted, and may, in some instances, be retained for years without occasioning any serious symptoms. When the more fluid parts have been absorbed, the more solid constituents remain, forming a pap-like mass of the consistence and aspect of moist cheese, or of imperfectly-coagulated white of egg. “Previously to this, the effused product usually sinks

to the most dependent part of the cavity of the pleura, so that the above mass accumulates into a layer more or less thick, between the two firmly-adhering and thickened pleuræ, posterior to the inferior lobe of the lung." When tubercle enters into the combination, and the case does not prove rapidly fatal, it is occasionally met with as a residue of the aggregate morbid product in small scattered portions included between the pleuritic adhesions. In such cases, various consecutive changes sometimes take place, which will be noticed hereafter.

125. *l.* When the fluid, instead of being removed by absorption, makes its way out of the pleural cavity, the lung is the part most frequently perforated; and it is the superior anterior portion of the organ which is most commonly the seat of perforation. HASSE states that this does not take place where the lung has suffered compression, but where it has continued to expand—in the majority of cases, at the inferior surface of the upper and middle lobes. Such portions are commonly attached by old adhesions to the costal pleura, and form an arch over the effusion. The effusion presses against this arch, until some point of the substance of the lungs and of the pleura softens, gives way, and allows the fluid to escape through the bronchi. The perforation may, however, take place at the inferior lobe, or at the base of the lung, especially when protected from compression by old adhesions, and remaining partially pervious to air. These perforations are rounded or oval, are smooth at their edges, and seldom exceed two or three lines in diameter. They are generally single. The parenchyma in the vicinity of the perforation or fistula is generally in a state of gray hepatization, or of complete purulent softening. This change is usually fatal; but ANDRAL and HEYFELDER have met with instances of recovery.

126. The passage of empyema through the diaphragm is very rare. ANDRAL and MOHR have adduced instances of this occurrence. In these the fluid, after perforating the diaphragm, pushed down the peritoneum before it, thereby preventing effusion into the peritoneal sac. In one of MOHR's cases the diaphragm was perforated near to the spine, and the pus descended behind the peritoneum, along the psoas muscle, causing abscesses and fistulous openings in the thigh, extending as low as the knee. GENDRIN mentions a case in which the fluid made its way into the anterior of the mediastinum. Escape of the effusion through the thoracic parietes presents a better chance of escape for the patient than the foregoing. The chief cause of the spontaneous evacuation of the fluid of empyema through the bronchi and thoracic parietes being so often fatal, is the influence of the external air upon the diseased pleura and upon the walls of the fistula, especially upon the substance of the lungs. The purulent secretion soon becomes remarkably fetid, and the air which passes into the cavity is soon deprived of its oxygen. DAVY found the air in pneumothorax to consist of 0.92 of nitrogen, and 0.08 of carbonic acid. The fluid of empyema generally evolves the odour of phosphureted and sulphureted hydrogen.

127. *m.* The state of the lungs, in cases where the pleural cavity is surcharged with effusion, has been described by several modern writers.

The lung of the affected side suffers the most, as may be expected, its compression being commensurate with the increase and ascent of the fluid, until it can no longer expand, and the air can scarcely enter the partially compressed bronchial tubes. When the lung is free from adhesions, it is pressed upward and forward, and finally on all sides towards its roots, when the bronchi and blood-vessels penetrate. It then occupies the least possible space in front of the vertebral column; is flattened and shrivelled; its different lobes are mostly adherent; the parenchyma is inelastic, devoid of crepitation, and almost bloodless; and generally without tubercles. When, however, tubercles are developed in the course of chronic pleurisy, or are advanced, having previously existed—a thing by no means rare—they are not found in the most compressed portions of lung. The bronchial tubes are usually found loaded with a whitish, tough mucus. Where adhesions exist, these generally preserve a portion of lung more or less expanded, the bronchi then remaining partially pervious to the air, and tubercles are not unfrequently seen in the partially-expanded portions of lung.

128. The mode in which compression of the lung presents itself in those cases in which adhesion between the opposite surfaces of the pleura exist has been described by MOHR (*op. cit.*, p. 127). Out of forty-three cases, six of which were double, the compression and displacement of the lung were once in the direction from above, downward; four times from behind, forward; four times from before, backward; four times from within, outward; thirteen times from below, upward; and twenty-three times from without, inward.

129. *n.* The appearance and structure of the adhesions formed between the lung and costal pleura, and between the lobes, differ; but they may be referred to two kinds: *First*, the cellular, in which the opposite surfaces are equally united by means of a dense cellular tissue; and, *secondly*, the filamentous or band-like, separate bridles or bands, having a smooth, serous surface passing between the two pleural surfaces. These bands appear identical with the serous membrane, whose product they are, and into which they directly pass. They are often supplied with blood-vessels of considerable size; and they consist of densely stratified cellular tissue, with an investment of epithelium cells; and they sometimes contain, as remarked by LAENNEC, HASSE, and myself, a considerable portion of fat within this texture, more especially in their centres (see above, § 100.) As shown by BECLARD, DUPUYTREN, VILLERMÉ, and others, these adhesions may remain during life without occasioning any sign of disease; but I have met with cases in which their existence and situation have been inferred, and the inference has proved correct, as shown by dissection, years afterward. They may even disappear in the course of time. In the latter case the chords lengthen, become thinner in the middle, and ultimately rupture, nothing excepting a whitish, rugose thickening of the pleura remaining.

130. The adhesions following and complicating tubercular disease of the lungs are different from those observed in primary pleurisy. They commence at the apex and gradually de-

scend, closely following the course and extension of the tubercular disease. Professor HASSE considers these adhesions as being less the result of decided inflammation than of a chronic irritation, limited in degree, and kept up by the proximity of the heterologous product. The result is complete blending of the pulmonary with the costal pleura, with lardaceous thickening, and degeneration of the serous structure. Owing to this intimate fusion, the intercostal vessels push branches into the diseased substance of the lung. In favorable circumstances to the development of inflammation, the slight irritation, causing the insensible, or nearly insensible, adhesion of opposite portions of the pleura, may amount to actual inflammation, rapidly spreading over the pleura, and throwing out diverse products, generally with tubercular matter, and passing into chronic pleurisy. MOHR calculates the complication of pleurisy with tubercular diseases of the lungs to be fifteen cases out of twenty; and this appears to be near the truth.

131. o. It is comparatively rare to find pleuritic lesions simultaneously in both cavities. HASSE states, that of thirty-five fatal cases he found nine double cases; and in five of the nine one sac was implicated in a minor degree. He considers both sides of the chest to be almost equally prone to the disease, with this difference, that pleurisy of the left side is both more likely to prove fatal in the acute stage, and more apt to pass into a chronic state; but he adds, of the thirty-five cases just mentioned, sixteen were of the left side, and ten of the right, the other cases being double. Of fifty-six cases observed by MOHR, the left side was the seat thirty-seven times, and the right nineteen times. The experience of Dr. H. ROE and Dr. HUGHES, also, shows a much greater frequency of the disease of the left than of the right side; and the cases which I have seen, since my attention has been directed to the matter, also evince a much greater frequency of pleurisy of the left side. In 1846 I met with four cases of the disease in this side in succession.

132. MM. RILLIET and RARTHEZ state, that simple pleurisy is more frequently met with in the right than in the left side in *children*; but that pleurisy complicated with pneumonia occurs oftener in the left; while the simple and complicated cases united are more frequently seen in the left than in the right. Of all the products of inflammation in this class of subjects, these physicians found that false membranes were the most frequent, and these were sometimes the only lesion; next to these was a turbid serum, a purulent fluid being the most rare.

In 85 cases, false membranes were present in 79.	{	In the right pleura only, 27.
		In the left only, 33.
		In the two cavities, 14.
In the 79 cases in which there were false membranes, they existed alone or with redness only, 28 times.	{	In the right pleura only, 14.
		In the left alone, 13.
		In both, 1.

133 VIII. THE DIAGNOSIS OF PLEURISY requires only a very brief notice, after the full descriptions which have been given above of

the symptoms, signs, and consequences of the disease.—a. The greatest difficulties as to diagnosis present themselves in cases occurring in *children*, and in *adults* when the physician has not observed the earlier stages, or when the pleurisy is latent, and the quantity of fluid effused is not great. In infants and children under four or five years pleurisy is most frequently associated with pneumonia; but after that age it is often primary and uncomplicated. During *infancy*, pleurisy is detected with great difficulty; but it should be dreaded when the patient is seized with violent and constant crying or screaming, restlessness, hot and dry skin, dry, short cough, and the appearance of increased suffering upon being raised to the erect posture. Upon inspection of the chest, the side affected does not move so freely as the other during respiration, and auscultation detects a rubbing or creaking sound, which usually continues longer than in adults. In very young children there are generally also signs of pneumonia, especially crepitation, associated with these, and occasionally there is evidence, moreover, of bronchitis. In older children pleurisy is also often complicated with pneumonia, and, in rarer instances, with pericarditis; but in these latter, acute rheumatism is generally also present, or it has immediately preceded the thoracic complication. The chief difficulty, however, is in distinguishing pleurisy from pneumonia, and in ascertaining during life the existence of the association of the two diseases. The former usually commences in children with dry cough and acute pain, soon followed by a bronchial respiration, inspiration being attended by a metallic sound, while the respiratory sound is rarely much impaired, unless the disease is advanced. Change of position aggravates the symptoms. The febrile symptoms generally abate from the fourth to the seventh day; and previously the rubbing or creaking sound is often heard, especially before effusion has taken place; but this sound may also be present when the lung is implicated. In this latter case, there are generally also crepitation or sub-crepitation, accompanying bronchial respiration and mucous expectoration, which in older children is often copious and even tinged with blood. When the lungs are thus also affected, the febrile symptoms are usually more severe, and continue until the 7th, 8th, or 9th day, before they abate.

134. b. In the earliest stage, the pain of pleurisy may be mistaken for *pleurodynia*, or nervous pain in the side; for the absence of any distinctive physical sign at this period, unless in such cases as may furnish a rubbing or cracking sound, leaves us without proof of the existence of the disease, excepting that which may be inferred from short, dry cough, heat of skin, hardness or sharpness of the pulse, and other febrile symptoms, and these may be very slight, or insufficient to indicate the nature of the malady. But not only may these be so slight as to be almost wanting, unless occasionally towards evening, but pain itself may be wanting, or be so situated, and so slight, unless in motion or on exertion, as to render the disease entirely latent, as stated above (§ 49), until the effusion is so considerable, as it usually is in a short time, in these cases, as to develop the physical signs (§ 24).

135. *c.* Pleurisy may also be mistaken for *consolidation of the lung*, and this latter for it. This mistake is most likely to be made when the pleurisy is attended by a moderate amount of effusion, the walls and contents of the chest not being displaced. This lesion of the lung generally increases the vocal resonance of the affected side, whether heard or felt by the hand, and allows some sound of respiration, which is generally of a bronchial character, to be heard; and it thus may be distinguished from this state of pleurisy. "Partial pleurisies confined by adhesions," as Dr. WILLIAMS justly observes, "are less easily distinguished, because, where the lung is adherent, there may be as much bronchophony and respiration as in cases of consolidation; but, on examination, these will be found to be more circumscribed than in the latter case, all sound being absent in other parts, which farther present the signs of enlargement or displacement of the heart, liver, or mediastinum, with fulness of the intercostal spaces, generally more remarkably than usual. A similar irregularity in the shape of the chest will serve to distinguish pleurisy in the progress of cure by contraction of the chest, from the case of a consolidated lung." (*Op. Cit.*, p. 122.) Although I admit the truthfulness of these remarks, as respects many cases, yet others will occur to which they do not apply, and in which they cannot assist the diagnosis. They apply chiefly to the more developed and well-defined cases; but to others not so characterized, and to those which are more complicated, they will furnish but slight aids. Indeed, no precise statements can be offered as to the diagnosis of several states of pleurisy attended by adhesions, partial effusions, and alterations of the substance of the lungs, as none apply sufficiently to these ever-varying states to mark them with precision. The physician's accuracy of diagnosis, as regards them, will depend much upon the attention with which he has watched the course of the disease, and upon his acumen in detecting, and his sagacity in comparing and estimating signs, symptoms, and almost imperceptible and evanescent phenomena.

136. *d.* Chronic pleurisy is liable to be confounded with *tuberculous disease of the lung*, for some of the signs of both maladies are somewhat similar, and the constitutional symptoms and affection are often alike. Indeed, the one may pass into the other, or both may be present. There never is, however, the same amount of dullness on percussion and absence of respiration in the latter malady as in chronic pleurisy; while the enlargement of the side and displacement of the viscera, attending pleurisy with very copious effusion and empyema, never exist in phthisis. The puriform state of the expectoration, often observed at an advanced stage of chronic pleurisy, should not mislead the physician, for this appearance of the sputum occurs in the last stages of most diseases of the chest, and is an attendant upon a sympathetic chronic bronchitis, which gradually supervenes in their advanced progress, and is independent of any actual disease of the substance of the lung.

137. *e.* Protrusion of the intercostals may be looked upon as the surest sign of *empyema*; for it rarely accompanies a very copious and non-purulent effusion in the acute stage, while it is

generally present when the fluid is purulent, although actually smaller in quantity than before it assumed this character; this sign indicating rather the kind of fluid than the quantity, as justly insisted upon by Dr. STOKES and Dr. H. ROE. It should also be recollected that a small effusion into the right cavity may, when the patient is examined in the sitting or standing position, be mistaken for an enlarged liver, or the rising of this organ high in the thorax, or this latter may be mistaken for the former; while the presence of a considerable quantity of fluid in the left side may not be detected, owing to an inflated stomach having pushed the diaphragm before or behind it, or to the small quantity of fluid interposed between the parietes and the inflated organ, admitting of a clear sound upon a strong percussion, although a dull sound may be given out by a very gentle percussion. The absence of the vibratory thrill produced by the voice, and the decubitus, generally on the affected side (§ 30, *et seq.*), will farther determine the seat of effusion.

138. At an advanced period of empyema a copious expectoration of purulent matter may occur, and may lead to the inference of the existence of a pneumonic abscess, or of a tubercular cavity, or, at least, of chronic bronchitis, of the uncompressed lung. Instances of this kind have been noticed by ANDRAL, STOKES, and MAC DONNELL, and upon dissection no such complication could be detected. But true pulmonic abscesses are comparatively rare, and are not accompanied with copious expectoration. The last writer just named very justly infers that purulent expectoration in empyema, although attended by quick pulse, sweating, emaciation, and other hectic symptoms, is indicative of tubercular or pneumonic abscess, unless attended by unequivocal physical signs of these lesions; but, on the contrary, it is to be regarded as the consequence of an effort of the constitution to get rid of a large collection of purulent matter by one of the ordinary emunctories.

139. It should, however, be kept in recollection that the lung of the sound side often experiences, in the course of empyema, congestion of the mucous membrane of its bronchi, or fully-developed bronchitis, often passing into chronic bronchitis. In such cases the accession of chills, rigours, fever, increased difficulty of breathing, with the physical signs of bronchitis, generally indicate the complication, which in various degrees is a frequent consequence of the increased determination of blood that takes place to the sound lung, owing chiefly to the compressed and impermeable state of the lung of the affected side.

140. When a circumscribed purulent collection forms on the left side and advances externally ("the *empyema of necessity*" of French pathologists (§ 52, 56)), it may, owing to the pulsations of the heart communicated to it, be mistaken for a thoracic aneurism, or even for a malignant tumour in that situation. Mr. MAC DONNELL has pointed out this circumstance, and has published some interesting cases illustrative of this form of empyema, which he denominates "*pulsating empyema of necessity*." It may be distinguished from *thoracic aneurism*, (a) by the history of the case; (b) by the dullness extending over the whole side, the pulsation being felt only in the external tumour; (c)

by the absence of thrill, and of bellows sound ; and (*d*) by the extent and nature of the fluctuation. It cannot be mistaken for *encephaloid*, or other malignant disease, if the progress of the disease, and the existing phenomena, have received even tolerable attention. The absence of a persistent bronchitis, of a dark expectoration resembling black-current jelly, and the absence, also, of a varicose or enlarged state of the veins of the surface, and of œdema of the side affected, will assist the diagnosis.

141. It was shown by me in 1815, and on subsequent occasions in 1820, 1824 (see *Med. and Phys. Journ.*, vol. xlv., p. 530, and Notes to RICHERAND's Physiology, p. 626), long before the subject was noticed by TRIEDEMANN, GMELIN, LIEBIG, and others, that, when the functions of the lungs are in any way impeded, the liver often performs a vicariously increased function, thereby preserving the blood from the impure or morbid state into which it would otherwise pass. This increased function of the liver is very generally remarked in the course of empyema. But, in addition to increased function, there also not unfrequently supervene congestion, and more or less enlargement of the liver, owing to the difficult or impeded circulation of blood through the lungs, and the equally impeded return of it from the hepatic vein. This enlarged, or at least congested, state of the liver, in most cases of empyema of any considerable duration, should not be overlooked, or mistaken for a partial empyema of the right side, which, however, it may accompany as well as empyema of the left side. The enlargement of the liver from congestion, or from impeded and impaired function of the lungs, generally supervenes to the vicariously increased action of the organ, and is observed chiefly in the more chronic cases of empyema.

142. *f*. The diagnosis between pleurisy with effusion and *hydrothorax*, and between empyema and this latter, is by no means easy, unless the history of the case be well known. The circumstance of *hydrothorax* being generally consequent upon disease of the heart, upon a far advanced stage of disease of the lungs, especially congestive pneumonia, œdema of the lungs, &c., or upon the last stage of other forms of dropsy, as ascites, anasarca, &c., is sufficient to prevent any difficulty in the great majority of cases to which the term *hydrothorax* is strictly applicable. Yet passive effusion may occur, although in comparatively rare instances, either in one or in both lungs, and be distinguished with difficulty from the asthenic and latent forms of pleurisy, more especially when the passive effusion is confined to one side of the chest, which is seldom the case when altogether independent of inflammation of the pleura. When dropsy of the pleura, however, is caused by disease of the lungs, it is then generally confined to the same side as the affected lung, or is greatest on that side.

143. In most cases, the chief differences that can be observed between chronic pleurisy or empyema and *hydrothorax* are, that the dilatation of the intercostal spaces is comparatively slight in *hydrothorax*, while protrusion of them or of the diaphragm is not observed in this latter. Dr. STOKES imputes this circumstance chiefly to the pathological state of the pleura and the adjoining muscles, and to the puriform

character of the effused fluid ; but something may also be imputed to the amount of effusion, which is rarely so great in either pleura in pure *hydrothorax* as in pleurisy, and hence a change of sound, varying with the position of the patient, may generally be recognised in *hydrothorax*, unless the passive effusion is consequent upon the existence of several old pleuritic adhesions. Dr. STOKES adverts to the following diagnosis between empyema and *hydrothorax*, as given by HIPPOCRATES and noticed by LAENNEC: "You shall know by this that the chest contains water, and not pus, if, on applying the ear during a certain time on the side, you perceive a noise like that of boiling vinegar ;" and remarks that, when we consider the conditions of the lung in empyema and *hydrothorax*, the diagnosis of HIPPOCRATES seems much more accurate than LAENNEC has admitted. In empyema the lung is but rarely affected, and no râle is heard, "no sound of boiling vinegar ;" while *hydrothorax* rarely occurs without more or less œdema or congestion of the lung ; so that, the presence of liquid in the chest being admitted, the occurrence of râle would indicate *hydrothorax* rather than empyema.

144. IX. PROGNOSIS.—The prognosis of pleurisy depends upon the form, state, and progress of the disease; upon the previous health and age of the patient ; upon the rapidity and amount of the effusion ; and upon the duration of the malady, in connexion with the treatment which has been employed. The sthenic forms of the disease occurring in previously healthy persons, and brought early under treatment, although serious in their consequences, and therefore requiring a most watchful attention, generally yield to judicious treatment, especially when employed promptly, or before effusion into the pleural cavity has become abundant. If, however, pleurisy have been neglected, or improperly treated ; if it have attacked a cachectic or broken-down constitution, or assumed an asthenic form ; if it have been latent, and hence existed for some time before it was recognised ; if it have supervened upon disease of the lungs, heart, liver, or peritoneum—more especially upon tuberculous deposits in the lungs, it is a most dangerous, and in the latter circumstances more especially, even fatal malady.

145. When the disease attacks a person who has been exposed to depressing agents ; to cold, humidity, insufficient nourishment, and anxiety of mind ; when the effusion increases rapidly, notwithstanding the employment of judicious means of cure ; when it appears in the scrofulous diathesis, or affects the pleura of both sides, or is attended by purulent expectoration, emaciation, or night sweats, or when the constitutional symptoms assume the hectic character ; when debility increases, and the urine becomes scanty, or œdema of the extremities supervenes ; and especially when these very unfavourable symptoms advance or continue for some time, the danger should be considered as very great, more particularly in the latter circumstances now enumerated. The prognosis in the complicated, the chronic, and the empyemic states of the malady is always very unfavourable, but more especially when occurring in the debilitated, the cachectic, and intemperate ; the amount of danger being generally extreme when the disease has for some time re-

sisted the usual remedies, or when the constitutional powers give way.

146. In those cases of empyema in which the matter finds its way through the lungs or external parietes of the chest, although the danger is great, still recovery may take place if the vital influence be not much impaired, if hectic symptoms be not developed, and if extensive disorganization be not present. The strength, constitution, and age of the patient, in connexion with the other circumstances of the case, should guide opinion as to the result. In the great majority of instances, however, the spontaneous evacuation of the fluid affords only temporary relief, the subsequent discharge and the hectic fever ultimately sinking the patient. The prolonged retention of the matter, and the consecutive changes in the lungs and parts adjoining the fluid collection, before a spontaneous discharge can be effected, generally sink the constitutional powers, and prevent a restoration of the lesions which have taken place, which are, however, usually too extensive to admit of restoration under any circumstances. Those cases in which the discharge is procured by operation admit of a much more favourable prognosis, especially when the operation has not been too long delayed, or until the alterations of the lungs and adjoining organs and parts are not rendered too great to admit even of a partial removal; but in these cases the result much depends upon the peculiarities of the case, and the circumstances under which the operation is performed.

147. Acute pleurisy seldom proves fatal increfely from the amount of the effusion, until it is passing, or has passed, into the chronic state; and even then, so rapid a termination is met with chiefly in the cachectic, and in cases of double pleurisy, or when previous disease exists in the lungs or some other viscus. The rapid accumulation of the fluid, however, is a very unfavourable occurrence in any circumstances of the case, as it indicates great defect of constitutional power, and an inability to effect its removal. An opinion of the result cannot be formed correctly in any case of the disease, until the more acute symptoms have subsided, or until the effects of the means usually employed for this purpose become apparent; and then the issue depends much upon the age and constitution of the patient. When the sounds of percussion and respiration return, however gradually, and the other symptoms and signs disappear, a doubt need not be entertained of a favourable result, especially if the lungs furnish no indication of disease.

148. X. PLEURA-PNEUMONIA—*Pleuro-pneumonia*—*Pleuro-pneumonitis*—*Peripneumonia*—*Peripneumony*, &c.—or the association of inflammation of the pleura with that of the substance of the lung, is so frequent, that these distinct diseases have been very often treated of as one, and with the belief that the one does not occur without the other. This, however, has been shown not to be the case, although they are frequently conjoined, as I have shown above, and when treating of inflammation of the lungs (see art. LUNGS, § 73, *et seq.*). The intimate connexion subsisting between inflammations of the pleura and of the pulmonary parenchyma, and the frequent complication of these diseases, lead me further to remark, that *pleura-pneumonia* presents itself in practice in three states, which pre-

sent certain differences in their progress, according as either tissue is prominently affected: 1st. *Pneumonia* associated with slight pleurisy; 2d. *Pleurisy* complicated with slight pneumonia; and, 3d. *Pleura-pneumonia* properly so called, in which the two affections seem nearly equal in degree.

149. i. *Pneumonia associated with slight Pleurisy*.—In those cases in which inflammation of the lung reaches to the pleura, in any point, lymph is thrown out upon the free surface of that portion of pleura; but in persons of a previously healthy constitution, the lymph effused is usually in small quantity, forming a false membrane, which extends no farther than the portion of pleura covering the inflamed or hepatized portion of lung immediately underneath. If the disease be of the sthenic character, or if it be unconnected with cachexia, constitutional vice, or a contaminated state of the circulating fluids, the inflammation, thus extending to a portion only of the pulmonary pleura, does not spread over the surface of this membrane, although the lymph thrown out will frequently excite a corresponding irritation or inflammation of the portion of the costal pleura with which it comes in contact, and thereby give rise to adhesions between the opposite surfaces. If the pneumonia and consequent hepatization occupy a portion only of the lung, the effusion on the serous surface is only slight, consisting of a sero-albuminous, or sero-puriform exudation. But if nearly the whole lung be affected, then there is often little or no effusion, a very thin or imperfect false membrane only being seen on its serous surface, which is thicker along the edges and in the interlobular fissures, and in some other points when the inflammation had first reached this surface. This is a very common form of *dry pleurisy*, complicated with pneumonia; and in this complication the pleurisy is merely contingent upon the pneumonia, and scarcely at all modifies the severity or progress of the primary disease. M. LAENNEC remarks, that it would be very difficult to distinguish this particular complication from a pleurisy with copious effusion, if the patient had not been seen before this period; the absence of the thoracic resonance is here as complete as if the whole surface of the lung were covered by a pleuritic effusion, while the stitch in the side commonly attending the extension of the inflammation to the pleura would farther induce the belief that the disease was simple pleurisy. When, however, the lung is completely hepatized, without any attending effusion into the pleural cavity, there is always a strongly marked bronchopneumonia in different points, and particularly toward the summit and root of the lung: a sign which never exists in the same degree, or over the same extent, in pleurisy or pleuropneumonia. If the patient have been seen from the origin of the disease, the diagnosis is much more easy. If the disease be pneumonia, crepitation will have been heard previously to the complete cessation of the respiratory murmur; and the gradual diminution of the resonance on percussion, and the supervention of a friction or rubbing sound, as described when treating of the *dry form* of pleurisy (§ 42, *et seq.*), will leave no doubt of the nature of the affection. In pleurisy the loss of resonance is very rapid, and exists, if the lungs have been previously

healthy and without adhesions, over the whole of the affected side. Œgophony, moreover, is always perceptible, at least for one or two days.

150. ii. *Pleurisy complicated with slight Pneumonia*.—If the pleuritic attack be severe, and the effusion so rapid and abundant as suddenly to compress the lung, it is not uncommon for inflammation of some points of the pulmonary substance to occur, particularly in the lower lobe. These points sometimes remain distinct and of small extent, constituting one of the varieties of *lobular pneumonia*. The pulmonary inflammation is here much modified by the pleuritic effusion, as I have shown in the article *LUNGS* (§ 73), and it rarely extends much farther than a few lobules, and still more rarely advances to suppuration. This complication can only take place early in the attack, and before the effusion and consequent compression of the lung have become very considerable; as a lung greatly compressed is hardly susceptible of inflammation, the *symptoms* and *signs* of this complication are described in the article now referred to (§ 75).

151. iii. *Pleuro-pneumonia, properly so called*.—The association of an inflammation of the whole or part of the pleura, with considerable effusion, and of a severe pneumonia, is not so frequently met with as either of the two complications just mentioned. M. LAËNNÉC remarks, that pleurisy conjoined with pneumonia does not increase the danger of the latter; on the contrary, it lessens the danger, as above stated, by compressing the lung. On the other hand, the pneumonia at first augments the danger of the pleurisy, which is rarely fatal in the acute stage; but it favours a more rapid absorption of the effusion, by preventing this from becoming as copious as in simple pleurisy, the inflammation rendering the lung less compressible. Hence pleuro-pneumonia, *ceteris paribus*, may be regarded as less dangerous than either simple pleurisy or simple pneumonia.

152. Pleuro-pneumonia is recognised by the union of the signs of pleurisy and of pneumonia; and some of these signs are even more permanent in this complication than in either of the simple affections; for they mutually impede and retard each other's progress when these inflammations are conjoined. The crepitation on the one hand, and the Œgophony on the other, are thus often heard up to the period of convalescence. In cases of this kind, Œgophony is seldom simple; it is perceptible only at the root of the lung, around the lower angle of the scapula; and, from the vicinity of the large bronchial trunks, and the density of the pulmonary substance, it is usually combined with marked bronchophony. This conjunction of these two signs LAËNNÉC has likened to the squeaking of Punchinello.

153. XI. TREATMENT.—i. HISTORY OF THE TREATMENT OF PLEURISY.—(a) Among the several means advised by the older writers for the cure of pleurisy, *blood-letting* was considered of the first importance; but there are various circumstances which have been noticed in connexion with it by these writers that deserve a brief notice. HIPPOCRATES advised bleeding “ad deliquium animi.” ARÉTÆUS insisted upon the necessity of early and repeated venesection, but cautioned against carrying it so far as to

produce syncope. He distinctly stated the nature and seat of the disease, and remarked that it was neither sporadic nor epidemic. AËTIUS was the first to point out some of the conditions which indicate the impropriety of having recourse to blood-letting, and imputed these conditions to indigestion and crudities of the stomach. CÆLIUS AURELIANUS and other Methodists advised blood-letting, but condemned the practice of carrying it to the length of causing syncope. ALEXANDER TRALLIANUS seems to have been the first to advise local depletion for this disease, according to the manner of cupping then in use. AVICENNA, and other Arabian physicians, generally had recourse to venesection and cupping, and the rest of the antiphlogistic plan.

154. The question as to the greater efficacy of bleeding from the same side as that affected in pleurisy, or from the opposite side, was agitated at a very early period. The Greek and Latin authorities were divided in opinion as to this question. HIPPOCRATES, GALEN, and CELSUS advised bleeding from the arm of the affected side; while ARÉTÆUS, AËTIUS, and CÆLIUS AURELIANUS directed it from the opposite side. The discussion was carried down by the Arabians, who, however, generally bled from the arm of the unaffected side; and by the writers of the fifteenth, sixteenth, and seventeenth centuries, some of whom, as AMATUS LUSITANUS, VESALIUS, TRINCARELLI, RULAND, SALLANS, WIPACHER, RODRIGUEZ, BERTIN, and others, discussed the subject as one of the utmost importance.

155. Other circumstances, of greater moment than this, were at last noticed in connexion with bleeding for pleurisy, by SYDENHAM, CALLISEN, BAGLIVI, and others, who insisted upon the injurious tendency of bleeding in cachectic and asthenic states of the disease, or when the blood did not present a buffed or cupped appearance. MURSIGNA, STOLL, and many recent writers have likewise cautioned against bleeding in these cases, as well as in those which present a putrid character, or a bilious in connexion with an asthenic diathesis; and have likewise warned the inexperienced against repeating venesection, or carrying it too far merely because the blood was buffed: a caution of no small importance.

156. There can be no doubt of pleurisy being much more prevalent at some seasons or in certain years than at others, and thus assuming, according to the circumstances of season or locality, more or less of an *endemic*, or an *epidemic* form; and there is no less doubt of the character of the disease varying remarkably at different periods and in distinct localities; it being, in one or the other, of a much more phlogistic and acute form than in the rest, or assuming even an asthenic or latent character. And hence, indeed, may arise the fact that blood-letting and other parts of the antiphlogistic treatment have been advised with very different degrees of boldness by different writers. We find that, since the days of GALEN, prejudices existed in Rome against large bleedings in this and other acute diseases; and these were very probably well founded, in respect of that and all other large cities in ancient times, as they are as regards this city and other large towns at the present day. The opinions of medical writers are

too generally based upon the narrow or peculiar circumstances of their own practice, either previously to or at the time of their writing; and all have neither the inclination nor the time to acknowledge the change of opinions which farther experience and more diversified opportunities have occasioned. We find that DOVER, CLEGHORN, HUXHAM, and many others advised very large, prompt, and repeated venesection; and that RIVIERUS, LE MERCIER, STOLL, and SIMS recommended that it should be performed in both arms at the same time. A more enlightened experience, and more diversified opportunities of observation, have now demonstrated that this practice may have been appropriate in many of the circumstances in which these writers had recourse to it; but that there are other circumstances, in respect not only of the individual, but also of the season, locality, and epidemic constitution, which render it altogether unsuitable and injurious; while there are certain conditions of the disease which I have endeavoured to point out, that require very different or even opposite measures. In the more doubtful circumstances of the case, or when the propriety of bleeding from the arm, or of the repetition of such bleeding, admits of dispute, the application of leeches to the side, as advised by ZACUTUS LUSITANUS, SARCOMÉ, SCHMUCKER, and HUFELAND, should be resorted to.

157. (*b*) *Emetics* were formerly much resorted to, but they are now but little employed for the cure of pleurisy. They, however, have had the sanction of RIVIERUS, RULAND, BLEGNY, MURSINNA, MORGAGNI, WRIGHT, STOLL, TISSOT, ACKERMANN, and SCHELHAMMER; and I can add that, when they are discreetly prescribed, they are important aids in the treatment of most of the forms of the disease. They should not be exhibited until after bleeding has been resorted to in the more phlogistic cases. They will often relieve the dyspnoea and oppression attending the stage of effusion, and promote absorption, when judiciously selected and associated with other means which are suited to the circumstances of the case. *Purgatives* are much less beneficial than emetics in this disease. Very active purging is seldom requisite, unless when there are accumulations of excretions and morbid secretions to remove; but it is always necessary freely to promote the secreting and excreting actions of the abdominal viscera. Conformably with this principle, *diuretics* are generally beneficial, especially at an advanced period of the disease, or when effusion has taken place, and when conjoined with cooling diaphoretics or other appropriate measures.

158. (*c*) *Mercurials*, especially calomel, in full or even very large doses in the more acute cases, with antimonials, or opium, or with both, according to circumstances, are often, in this as well as in other inflammations of serous membranes, of the greatest advantage. They have been much recommended by LIND, WRIGHT, FINCH, HAMILTON, and others, and the experience of recent writers has confirmed the statements of their predecessors. The active exhibition of calomel, either alone or in the combinations now mentioned, is even more necessary in the early stages of pleuritis than in those of pneumonia; and, in the more advanced stages, or when effusion has taken place, either this or some other mercurial preparation, conjoined

with diaphoretics or diuretics, and aided by external rubefacients and derivents, is of the greatest benefit. I have often given the bichlorate in small doses, either thus associated, or with other tonics and alteratives, as cinchona, sarza, &c., with marked benefit, at an advanced stage of the disease, and more especially of the latent and asthenic forms.

159. (*d*) *Antimonials* are not so beneficial in pleurisy as in pneumonia, yet they have long possessed a high reputation in the former disease, and have been much confided in by AGRICOLA, MILLAR, BROCKLESBY, BELFOUR, LAENNEC, and many others. Of these preparations the kermes mineral and tartar emetic have been most employed, although the empirical powder of JAMES and others have also been prescribed with advantage. The kermes mineral was recommended by VON MERTENS, BANG, SIMS, MONTRAL, COLOMBIER, &c., in doses of one fourth or one third of a grain given every two or three hours, while the tartar emetic was adopted by CALLISEN, MILLAR, BELFOUR, LAENNEC, and numerous modern writers. Antimonials have rarely been confided in alone for the cure of pleurisy, but have usually been prescribed in aid of vascular depletions, and for the reduction of vascular action and the promotion of perspiration; the substances most beneficially conjoined with them being mercurials, opiates, and other sedatives, or cooling diaphoretics and diuretics, more particularly the solution of the acetate of ammonia, or of the nitrate of potash, and the nitric ether or the spirits of nitric ether.

160. (*e*) Opium and other narcotics have been used by several writers, but generally in combination with other medicines, according to the stage of the disease and circumstances of the case, and with the intention of allaying pain, and of promoting the operation of the substances with which they were conjoined; as with calomel by HAMILTON, to determine the constitutional operation of this medicine; with ipecacuanha and nitre by DOVER, to determine the diaphoretic action of these substances, or with diuretics to ensure their operation on the kidneys. Opium was much praised by KORUM for pleurisy; and certainly, in conjunction with calomel or other mercurials, and with an antimonial preparation, or in the form of DOVER's powder, as I have advised it in other inflammations of serous surfaces, it is of great service, especially after blood-letting in the more phlogistic cases; and with alteratives, or diaphoretics, or mercurials, &c., in the more advanced stages.

161. (*f*) Of other medicines which have been resorted to in pleurisy, there are few which deserve a particular notice. *Camphor* has been much praised by BAGLIVI, GRIMM, TISSOT, GRUELHANN, and SCHELHAMMER, especially in conjunction with nitre. I have prescribed this medicine very often in the more asthenic forms, and in advanced stages of the more sthenic stages of the disease, and frequently with great benefit, but generally with a mercurial alterative, or other substances, according to the circumstances of the case. *Ammonia* was employed by CHALMERS; HOFFMANN's *ether*, and other stimulants, by TISSOT; and *benzoin* by HOFFMANN; but they are serviceable chiefly in asthenic forms and contingent conditions of the

disease. I may add, that *aconite* was recommended by GEBEL, in combination with an antimonial medicine for the rheumatic form or complication of the disease, in which form, also, *arnica* was much used by several German writers.

162. (g) The *inhalation of warm vapour* was advised for pleurisy by HIPPOCRATES, and of numerous forms of warm, medicated vapours, by modern writers. I, however, much doubt their efficacy, unless as adjuvants, in this disease, in which, as well as in peripneumonia, this practice should not be overlooked, especially in cold and dry states of the atmosphere. In these circumstances of weather and of disease, I have had recourse to it on numerous occasions. In a case attended in 1826, by Dr. T. GORDON, Sir J. ANNESLEY, and myself, the vapour of boiling water was introduced into the apartment, and within the curtains of the bed, by means of a tube leading from a boiler on the fire of the room. As to the use of *medicated vapours*, I need add nothing to what I have stated respecting bronchitis (*see art. BRONCHI*, § 98, *et seq.*), as much of what I have there advanced is applicable to pleurisy as well as to pneumonia and bronchitis, and to most of these complications.

163. (h) *Demulcent and oleaginous medicines* were very generally employed by both ancient and modern writers, in expectation of obtaining a soothing effect from them as regarded the pain and the cough of pleurisy, and as a vehicle for more active substances. *Linseed oil*, and *decotions*, and *almond oil*, were chiefly thus prescribed by SYDENHAM, LANGE, SPINDLER, and others, and were often associated with *camphor*, *opium*, and other sedatives by GILBERT, DE HAEN, KORTUM, and numerous more recent authors. Many other demulcents and mucilaginous preparations have been used, as the *decocum althææ*, &c., but they require no farther notice at this place.

164. (i) Numerous *external means* were advised for pleurisy by most writers, from HIPPOCRATES to this time. *Warm fomentations* of various kinds, and both humid and dry, were much employed; and even *topical cold*, by evaporating lotions, or by means of ice or snow, as advised by BARTHOLINUS, was even resorted to. Of this latter but few modern physicians will form a favourable opinion, although certain analogical facts may be adduced in its favour. *Sinapisms*, and other rubefacient applications to the side affected, were advised by CELSUS and others of the ancients, as well as by the Arabian and modern writers; and they are certainly of more or less benefit, according to the knowledge by which a recourse to them is guided. The most beneficial rubefacient, however, which can be employed, the most appropriate to all circumstances of the disease, and the least liable to be injurious in any, is the *spirit of turpentine*, in the form either of epithem, or of liniment, or of embrocation, or conjoined with oil, or camphor, ammonia, and oil with opium; and repeated or renewed according to the effects produced, and to the peculiarities and complications of the case.

165. (k) *Vesicants* over the part affected were recommended by AMATUS LUSITANUS, CONRADI, BROCKLESBY, GARDANNE, GRIMM, THOMANN, DE HAEN, TRALLÉS, and ENGELHART. But they should be prescribed only after bleed-

ing in the more sthenic or phlogistic cases; be large, and repeated even oftener than once in the more chronic states of the disease; and be aided by mercurials, diuretics, and alteratives, according to circumstances. The propriety of applying them over the affected part, especially when there is reason to suppose that the costal pleura is inflamed, and when the patient is thin or emaciated, may be reasonably questioned. In these circumstances, I have generally directed them to be applied, either more or less below the seat of pain, or on the opposite side. In the more asthenic and chronic forms of the disease, a repetition of them, generally in quick succession, in different parts of the thorax, are often of great service, PLUMMER'S pill, with ipecacuanha and opium, being given at night, and small doses of the iodide of potassium and liquor potassæ, with sarsaparilla, being taken during the day. The repeated application of *moxas* to the affected side has been a common practice from the earliest ages in Eastern countries, and has been frequently had recourse to in Europe by modern physicians with considerable advantage in chronic cases of the disease. In these cases, as well as during convalescence from acute attacks, I have often prescribed a large plaster to be kept applied upon the affected side, consisting either of the emplastrum ammoniacum cum hydrargyro, or of a combination of this with the emplastrum picis compositum.

166. ii. TREATMENT ADVISED BY THE AUTHOR. —The *intentions of curæ* are nearly the same for the several forms of pleurisy, although each form requires a more or less marked modification of the plan and of the means by which these intentions are to be fulfilled. The *first* object is to arrest the progress of the inflammation; the *second*, to promote the removal of the products and the consequences of the inflammation; and the *third*, to enable the constitutional powers to resist, in the more chronic cases, the injurious influence of the structural changes produced, and, if possible, to counteract or overcome them.

167. A. IN STHENIC ACUTE PLEURISY, the obvious indication is to arrest the progress of the inflammation by the means recommended for other inflammations of this character affecting other serous tissues, namely, by *blood-letting* to an amount which the age and constitution of the patient, the hardness of the pulse, and the duration of the attack will suggest. If the patient be robust, if the disease has not advanced so far as to give rise to great effusion, and if the pulse be hard and inspiration painful, general bleeding should be promptly resorted to, and carried sufficiently far to relieve the respiration, and to make a decided impression on the pulse, without, however, producing full syncope, for the reasons stated in the article BLOOD (*see* § 64, *et seq.*). Contemporaneously, or nearly so, with the blood-letting, a full dose of *calomel*, *antimony*, or *ipecacuanha* and *opium*, should be given, taking care that the dose of the antimony or ipecacuanha should not be such as to occasion vomiting. The effect of these I have so frequently shown to be such as will promote the good effects of vascular depletion, and often prevent the necessity of repeating this measure, that I need not here recur to the subject. If, however, pain on in-

spiration, or when coughing, or hardness of the pulse, should return, blood-letting ought to be repeated, and the other medicines just named again be exhibited after the operation. In some cases, more especially if the patient be not very robust or be not plethoric, *local depletion*, by means of *cupping* a short distance from the spine, or of *leeches* near the part, may be employed in place of the second venesection; and, in more robust and plethoric persons, after the second blood-letting, if the pulse should rise, and the febrile symptoms increase. The application of leeches should be followed by a succession of warm poultices, or several folds of warm, moist cloths or flannels, covered by dry napkins.

168. It will generally be requisite to give some *purgative medicine*, in order to keep down febrile reaction, and derive the circulation from the seat of disease. But this medicine should not interfere with the effects of those just recommended, and therefore it ought not to be given until some hours afterward; and, during its operation, care should be taken to prevent the free perspiration, usually produced by the medicines previously given, from being checked. The purgative operation may be farther promoted, if it be required, by *clemata*, more especially such as contain the oleum ter-ebinthinæ, or may be left to them alone, particularly when the bowels are not confined. In addition to the means now advised, suitable *diaphoretics* should be given at short intervals. The most generally appropriate are those which consist of the liquor ammoniæ acetatis, spiritus ætheris nitrici, and either the vinum antimonii tartarizati or vinum ipecacuanhæ, with camphor water. To these may be added other medicines, such as digitalis or hyoscyamus, or both, as circumstances may suggest; or a preparation of colchicum may be substituted for the antimony or ipecacuanha, but its operation should be carefully watched.

169. In this form of the disease, and more especially if it have made considerable progress before it came under treatment, the repetition of the calomel with JAMES'S powder, or with ipecacuanha and opium, becomes necessary. The frequency of their exhibition should depend upon the dose prescribed and the urgency of the case. I have usually directed full or large doses, particularly of the calomel or opium, at intervals of six, eight, ten, or twelve hours, and the saline medicine, mentioned above, to be taken in the intervals, until the gums indicate a slight affection, or the evacuations assume a green or very dark hue.

170. The above treatment will generally accomplish the first intention, and the latter part of it partly fulfil the second. But it may happen that, when we have happily arrived thus far, exposure to a current of air, or some untoward circumstance, may occasion a *relapse*, or a *recrudescence* of the disease; and the physician will then propose to himself this question, Ought general blood-letting now to be resorted to, or should local depletion be confided in? In this state of the case he will duly consider the amount and effects of the previous vascular depletions, the duration of the disease, and the probable amount of effusion, the existing states of the pulse and of respiration, the pain and other symptoms, in connexion

with the age and constitution of the patient, and decide accordingly. But, if a due estimation of all these prevent him from venturing upon general blood-letting, he will decide in favor of the application of leeches, the number varying with the exigencies of the case; and he may even see occasion to repeat them, and to follow them with the warm poultices and fomentations already advised (§ 167).

171. In order to prevent the farther progress of the disease and its consequences, as well as to remove its more immediate results, additional means are often required, more especially after the inflammatory or acute symptoms are reduced. At first the *turpentine epithem* may be applied over the affected side, or folds of warm flannel moistened with this substance, or with embrocations containing a large proportion of it (see Form. 295, *ct seq.*). These may even suffice, and prevent the necessity of having recourse to other means; but if they do not produce a decidedly beneficial effect in the course of twenty-four or thirty-six hours, or little more, they should be replaced by a large *blister*, which will generally produce its effects in about six hours, when it should be removed, and the part be covered with a large warm bread-and-water poultice. This ought to be frequently renewed. It will rarely fail to procure a free discharge from the blistered surface.

172. If the disease has made considerable progress, or if the effusion is considerable, it will generally be requisite to keep up a slight mercurial effect on the gums, and to repeat the blister either over or near the part. But in no instance should the blisters, or the vesicating tissues employed in their stead, be applied longer than six or eight hours; they should be then replaced by warm poultices, which will cause them to rise, and prevent the inflammation produced by them from extending below the integuments. In some instances, particularly in those which have proved most obstinate, and when no mercurial effect has been produced, I have directed the blistered surface to be dressed with the mild mercurial ointment, or with this in part, and have generally seen benefit derived from the measure. If the disease be not cured by the above treatment—a contingency which generally arises from some complication or pre-existing affection, or from the advanced progress of the malady before it came under treatment, or from a constitutional vice, as the scrofulous or tubercular—it then assumes the *chronic form*, to which attention will be more particularly directed in the sequel.

173. B. THE ASTHENIC AND THE LATENT STATES OF PLEURISY (§ 47–50) are often advanced to a more or less copious effusion before they come under treatment; and for this reason, and still more from the state of the disease, they rarely admit of general blood-letting, unless they are seen at a very early stage, and the asthenic diathesis is not very prominent. An intimate knowledge of morbid actions, conjoined with close observation and an experienced recourse to remedial agents, can in no circumstances be more advantageously evinced than in the course of treating these and the preceding forms of pleurisy—in determining, in the sthenic, how far to carry, and

how often to repeat, vascular depletion, and in the asthenic and latent as to the propriety of adopting this practice, and as to the manner and the extent of carrying it out when it is determined upon. It should entirely depend upon the state of the pulse, the age and constitution of the patient, and the progress of the disease, whether a moderate blood-letting or leeches be prescribed. Cases may occur when both may be required, and others where neither is admissible, owing to the depression of vital power, and the great amount of fluid effusion which had taken place before the disease had come under treatment.

174. In these states—in those in which vascular depletions have been practiced, as well as in those in which they are inadmissible—recourse should be had, in a prompt and efficient manner, to alterative and diuretic remedies. If the effused fluid be not inferred to be of the puriform character—a state of the effused fluid very rarely observed in an early period, even of the asthenic and latent forms of the malady—calomel should be given, with opium and small quantities of camphor, twice or thrice a day; the infusion of digitalis, with the nitrate of potash, the spiritus ætheris nitrici and oxymel of squills, being taken in the intervals, in doses which the peculiarities of the case will suggest. The digitalis will be more certainly beneficial if it be given at first in as large doses as may be prudently exhibited, each dose, after the second or third, being diminished. The terebinthinate epithem or embrocation should, at the same time, be applied over the affected side, and be renewed according to the effect.

175. In cases of longer duration—when the disease has existed two or three weeks—and when the quantity of fluid effused is considerable, acute or inflammatory symptoms having subsided, the treatment should partly depend upon the means which had already been employed. If the patient be seen for the first time, the internal and external remedies just now mentioned should be resorted to; but if these or similar agents have been employed without avail, the pilula hydrarg. chloridi comp., with the pilula scillæ and digitalis, may be given night and morning, and two or three doses of the iodide of potassium in solution with the spiritus ætheris nitrici, or some other diuretic, in the course of the day. Blisters should not, at the same time, be overlooked; they may be repeated, according to circumstances, in the manner already recommended, in order to obtain their most beneficial effects, and to secure a free discharge from them. They are certainly beneficial, but not to the extent stated by some recent writers. In some instances I have prescribed the iodide of mercury internally, with small doses of squills and digitalis, with seeming advantage; and in others directed the iodide of lead to be used externally in the form of an ointment, according to the following formula, a small piece of it being well rubbed over the affected side every night, or both night and morning, the side being covered afterward by a piece of flannel:

No. 325. Plumbi Iodidi, ʒj; Unguenti Hydrarg. mitioris et Adipis præpar., ʒā ʒvj. Misce bene, et fiat unguentum.

176. The effects of iodide of potassium in this disease are very uncertain. In some I have found it very serviceable, in others of doubtful

advantage; and in a few I have considered it prejudicial. I have employed it in dropsical diseases of all kinds for very many years, since the time of its first preparation, and can, therefore, say, from considerable experience, that its effects should be carefully observed in the asthenic and latent forms of this disease; for, in some of the more extreme of these, it may prove, as I have found it in two or three cases, distressingly depressing, although given in very small doses. In these cases the iodide of iron, taken in sirup of sarza, may prove more serviceable, especially when aided by the continued application of the emplastrum ammoniaci cum hydrargyro, or by a plaster consisting of equal parts of this, and the emplastrum picis comp. In most cases of the disease, these last means will prove of great service in promoting the absorption of the fluid during early convalescence, or when the fluid is partly removed. At this period change of air—especially to a mild, pure, and dry air, or to the sea-side, in a sheltered situation, and suitable diet and regimen—avoiding vascular excitement, yet sufficiently supporting the powers of life, should always be recommended.

177. It is not unusual to observe, in the more asthenic cases of pleurisy especially, an abundant and rapidly-increasing effusion, occasioning the greatest distress, and even threatening the dissolution of the patient, by its pressure on, and displacement of the lungs, heart, and large vessels, notwithstanding a judicious recourse to internal and external means. When this result is met with, more especially in very delicate or scrofulous persons, or in the asthenic and latent states of the disease, the remedies already noticed having proved inefficacious, no farther time should be lost before recourse be had to *paracentesis thoracis*, to the removal of the fluid through an opening made in the parietes of the chest. It is obvious that, as soon as the medical treatment proves itself inefficacious, this operation should be resorted to, for delay will diminish the chances of success from its performance. As this operation is also required in the chronic states of the disease, more especially for empyema, it will be more particularly noticed hereafter.

178. *C. PARTIAL AND DOUBLE PLEURISY* (§ 51–62) require but little modification of the treatment already advised, which should be adapted to the peculiar features of individual cases. Where the symptoms are acute, and at the same time of the *sthenic* character, the antiphlogistic means should be employed accordingly, and with due reference to each feature of the case. When they partake more of the *asthenic* form, the measures mentioned in connexion with it then are requisite. It may be remarked that, while partial pleurisy more generally presents the former character, double pleurisy commonly possesses most of the latter, and especially requires prompt and efficient treatment, which, however, is in no way different from that which has been already advised.

179. *D. CHRONIC PLEURISY AND EMPYEMA.*—*a.* If the disease have become chronic before treatment has been employed, then the duration of the disease, the amount and probable nature of the effusion, and the urgency of the symptoms will suggest the measures which should be adopted. If the malady have become

chronic, owing to the failure of the means resorted to, or to the constitution of the patient, or to both causes conjoined, as usually observed, the question may still be entertained as to what may be farther tried. In the former circumstances, if the indications above stated (§ 137, *et seq.*) as to the purulent nature of the effusion be not present, and if the duration of the disease have not been above two or three weeks, then the internal and external treatment advised above (§ 174–177) may be tried—promptly and efficiently—before recourse shall be had to *paracentesis thoracis*. If, however, protrusion of the intercostal spaces, hectic and other symptoms indicate a puriform state of the pleural collection, no time should be lost before resorting to this operation. In the latter circumstances referred to, especially when the treatment has been judicious, no appropriate and efficient means having been overlooked, the operation is equally required, whatever may be the nature of the fluid collection, although, perhaps, it may be more urgently called for when indications of a purulent character are present; for where these indications exist no other means will save the patient. The several writers who agree in the propriety of having recourse to this operation—especially LARREY, J. P. FRANK, LAENNEC, FORBES, BELL, ELLIOTSON, WILLIAMS, DAVIS, and H. ROE—advise its performance when the effusion proceeds so rapidly as to threaten the life of the patient, or when it either increases or remains stationary under the use of the means already recommended, although the dyspnoea may not be urgent or the danger immediate, for the continuance of the morbid collection and the compressed state of the lungs may prevent this organ from recovering its functions. Dr. H. ROE justly remarks, that “for empyema paracentesis should always be performed the moment the nature of the case is ascertained. For serous effusions occurring in persons of scrofulous habits, or very delicate health, after pleuritic attacks, for the cure of which the necessary treatment has either failed or been neglected, paracentesis will generally be required.” (P. 208.)

180. *b.* There are certain *conditions* requisite to the success of the operation. It is most important that it should be performed before either the vital powers of the patient are too much reduced, or the thoracic viscera have undergone serious organic lesions. It is chiefly when the lung still possesses the power of expanding after the pressure upon it is withdrawn, that a cure can be effected without deformity of the side. If, however, the operation be delayed until the lung has become atrophied, condensed, or bound down by adhesions, so as to be incapable of expanding sufficiently to meet the ribs, either the vacuum will be rapidly refilled with fluid, or the shoulder will be depressed and the side contracted. This last change seldom occurs immediately after an operation, although it takes place gradually, and to a great extent, when the fluid is absorbed. The reaccumulation of the fluid will, therefore, be most likely to occur when the lung is incapable of expanding sufficiently after the operation. When this is the case, a space must necessarily intervene between the surfaces of the pleura, and either the fluid is thereby prevented from being drawn off during the operation, or it is replaced

by atmospheric air, which is always injurious to the pleural surfaces, and occasions a more puriform, and often an offensive renewal of the effusion, and the aggravation of both the local and constitutional symptoms, exhausting and ultimately destroying the patient. These consequences sufficiently show the propriety of an early recourse to the operation, but they are not satisfactory reasons for the neglect of it altogether, as urged by those who object to the performance of it.

181. When the operation is performed sufficiently early, even in the most rapid and urgent cases of empyema, the removal of the puriform collection allows the lung to expand, and the upper portions of the pleura to come in contact, and ultimately to adhere; and the adhesion gradually extends as the fluid is removed, until the opposite surfaces become agglutinated; and a cure is thus effected by the obliteration of the cavity throughout, or nearly so. In order to secure this desirable result, it would be most important to determine, were it possible, the exact period when the operation ought to be resorted to—when an operation would prevent the accession of those changes which usually become irremediable. It is manifest that, when indications appear of a puriform state of the collection, no delay should occur; and that, in many cases, it might be of advantage to ascertain, by means of the exploring needle, the exact nature of the effusion. If it be found that the fluid is serous, then Dr. H. ROE believes that we may wait till the end of the third week, in hopes that medical treatment may cause absorption; and, if it does not, that the operation should not be longer deferred; for he considers, and I think justly, that the operation should not be postponed to a later period, lest organic changes in the thoracic viscera may become irremediable, and that it is, therefore, better that it should be performed too soon, than that this risk should be incurred by delay. Cases are recorded of patients who had been tapped successfully for pleuritic effusions of several months' duration; but there was no proof that the lungs expanded to their full dimensions in those cases, and that the recovery was complete. Dr. ROE states, that no case has occurred to him in which the patient was *perfectly cured* when the operation was delayed until five or six weeks from the commencement of effusion. The non-expansion of the lung in these circumstances has always given rise to the introduction of more or less air into the cavity, in the cases which have come under my observation, however carefully the exclusion of it had been attempted; and the patient has usually sunk from a reaccumulation of a fetid purulent secretion, or survived with a considerable loss of lung.

182. *c.* The operation being manifestly necessary, in the circumstances now stated, and its performance not admitting of delay, the manner and the situation in which it is most advantageously performed requires some consideration. The situation in which the opening into the chest should be made has been pointed out by LAENNEC, and it has been generally adopted by later authorities. He recommends the space between the fifth and sixth ribs, a little behind the digitations of the serratus major, as being the most dependent point in the horizontal po-

sition, generally the freest from adhesion, and the seat of the greatest quantity of fluid. In this situation the operation was performed in all the cases recorded by Dr. H. Roe.

183. The manner of performing this operation has recently received due attention. Formerly surgeons advised operations implicating serous surfaces with a perfect indifference to the action of the air upon those surfaces. But the injurious action of the atmospheric air upon serous or shut cavities especially, and indeed upon other surfaces or parts denuded of their epithelia, or separated from their natural connexions, is now acknowledged by every enlightened observer. This is evidenced by the inflammatory irritation, terminating, in weak or unhealthy constitutions particularly, in offensive purulent discharges, and acute hectic fever. Of the three following modes of performing *paracentesis thoracis*, the one which should be adopted may be inferred from what I have just stated. According to one plan, an incision is made into an intercostal space, the fluid is evacuated at once, and the wound left open. Another method is to make an opening into the pleural cavity with a trocar, to keep the wound open by introducing a canula, or a catheter, or gum-elastic tube, by which the fluid is to pass off gradually. The third mode consists in making an opening by a trocar or otherwise, and allowing as much of the fluid to flow out as will escape without admitting the air, and in immediately closing the opening. This last method is that which I would recommend, from observation of the results of these several methods, and for the following reasons: *First*. When the air, even in small quantity, comes in contact, either with the pleural surface, or with the false membrane formed on this surface, the state of morbid action and the fluid secreted are still farther removed from the natural and healthy conditions, and rendered more injurious to the economy, and much less capable of restoration to states compatible with the continuance of life. *Secondly*. The continued access of the air will give rise to the thickening of the false membrane, and thereby prevent the lung from expanding, while it will render the secretion at first purulent, and afterward offensive and irritating to the surfaces containing it, and consecutively most contaminating to the circulation and whole frame. *Thirdly*. The operation performed so as to prevent the introduction of the air, although often required to be repeated at successive periods, closing the wound carefully in the intervals, admits of the gradual agglutination of the opposite surfaces of the pleura, does not interfere with the contingent absorption of the remaining fluid, and is compatible with the continued recourse to medical treatment appropriately to the peculiar features of the case.

184. I agree so entirely with what Dr. WILLIAMS has stated as to the manner in which this operation should be performed, that I here adopt his recommendation: "The spot for the introduction of the trocar should be determined with due reference to the physical signs; carefully avoiding every part where, or near which there is sound of respiration, voice, or not perfect dullness on percussion. A projection or fluctuation of an intercostal space give greater eligibility to a spot; and these circumstances

present themselves most frequently at the inferior lateral parts of the chest, from the third to the seventh rib, where, also, the soft walls of the chest are as thin as anywhere. In all cases it is a proper precaution to pass a grooved needle first, as recommended by Dr. T. DAVIES; for this at once determines the pressure of the fluid, its quality, and the thickness of the walls which contain it at that spot." The upper margin of the fifth or sixth rib offers most commonly the most favourable situation, avoiding, of course, the immediate vicinity of the known arteries and nerves, and especially of the heart, with reference to displacement, &c. "The patient should be lying on his back, inclining to the affected side, and not more raised than is necessary to the state of his breathing. The skin should be drawn aside, so that the puncture through it may not, after the trocar is withdrawn, correspond with that of the pleura, but form a valvular orifice. The trocar should not be pushed in farther than is necessary to clear the parietes, but the canula may be pushed farther after the stilette is withdrawn, and its sides should have several holes in them. As soon as the stilette is withdrawn, steady pressure should be applied by a bandage, or by the hands of an assistant, to depress the shoulder and sides, and to push up the diaphragm on the affected side to promote the flow of liquid, and to prevent the introduction of air through the orifice during any sudden or forcible act of inspiration. For the same reason, during a fit of coughing, if there appear any tendency to intermission in the stream of fluid, the orifice should be closed by the finger. The pressure should be steadily increased as the liquid flows; and if the stream should stop, a probe may be passed through the canula, to clear it of clots of lymph or other obstructing matter; but if still no more flows, a compress, or, if the liquid is purulent, a large poultice should be placed on the orifice; and then, and not till then, the pressure on the walls of the chest may be discontinued. The result will be, that the walls of the chest, expanding by their own elasticity on the removal of the pressure, will draw air into the compressed lung, which, being thus inflated, will begin to resume its part in the function of respiration and circulation, and will thus promote the absorption of the rest of the fluid, and improve the condition of the whole system. Even if the fluid should reaccumulate, the temporary expansion of the lung will have served to restore its natural properties, so that, when another quantity of fluid is again withdrawn, the organ will be better prepared for a restoration of its functions." (P. 28.)

185. Performed in the manner thus judiciously advised by Dr. WILLIAMS, the operation is free from risk, and will seldom fail to give relief. If the collection be purulent, it will often be necessary to repeat the operation several times; but if it be serous, one tapping, which will more or less expand the lung, will often be sufficient to give a turn to the disease, the complete removal of the effused fluid being effected by nature, aided by appropriate remedies. When the fluid is purulent, Dr. WILLIAMS recommends the injection of warm water with the view of displacing it; but, instead of doing this with a single tube, it should be done

through a double-cubed canula, the tube for injection being cautiously carried two or three inches into the chest, while the evacuating tube is merely long enough to pass through the walls. If warm distilled water be then thrown in by a syringe through the longer tube, it will drive the matter off through the shorter tube, and in this way the morbid secretion will be displaced by water, which is much more likely to be absorbed. If, after repeated evacuations, there be no apparent disposition to the expansion of the lung or contraction of the chest, and matter continues to be secreted, the writer now quoted advises a recourse to medicated injections, "such as a very weak solution of nitrate of silver, or chloride of soda." I have no experience of medicated injections in these circumstances; but I see no reason against a cautious recourse to them. The pleural sac may be treated, in these cases, as an abscess; and, if the discharge be unhealthy, we should endeavour to correct it, and to promote the healing of the diseased surface by such means as are found beneficial in analogous circumstances. When the discharge is fetid, it may be washed out, in the way just advised, by antiseptic injections, especially by chlorinated solutions, or fluids containing creasote. "The same practice may be advantageously pursued when the matter has pointed, and opened spontaneously, leaving a fistula which may remain open for months, or even years. Dr. TOWNSEND mentions the remarkable case of Dr. WANDELSTADT, who had been tapped thirteen years before, since which time the wound had remained open, and discharged daily from half a drachm to four ounces. The diseased side was much contracted, and did not move on breathing, yet he could blow the flute, walk fast, and actively perform his professional duties."

186. I believe that the HIPPOCRATIC method of evacuating the fluid at successive times, preventing the access of air, and closing the orifice in the intervals, is the best, because it gives the lungs time to expand, and prevents those changes in the inflamed membranes, and in the products of inflammation still retained in the pleura, that the admission of air would certainly produce. The practice of leaving the orifice open, and especially of leaving a canula in it, is attended by this mischief, namely, that the free access of air to the cavity either rekindles the inflammation of the pleura, of which the effusion had in great measure caused the resolution, or changes the character of the inflammation still remaining from an adhesive to a suppurating form, and ultimately even decomposes the matter which is formed. I have generally observed, when the access of air was allowed, that the fetor of the discharge was most manifest in two or three days, and that all the constitutional, and even the local, symptoms were aggravated.

187. Several recent writers, who have advocated the propriety of operating in the circumstances already stated, have not sufficiently recognised the importance of excluding the air, and have considered that, because it has been shown by the experiments of NYSTEN and others that air introduced into the cavity of the healthy pleura is removed in a short time by absorption without manifest detriment, no injury need be expected from its admission after

this operation. But circumstances are different as regards these experiments and the operation for this disease; besides, what has been inferred from *à priori* reasoning and from analogy has been proved by the experience of several candid observers, namely, that, although air may not affect a serous surface, when only temporarily brought in contact with this surface, it will certainly influence it, if allowed free communication with it; that, when this surface is inflamed already, the admission of air aggravates, and changes to an unfavourable form that inflammation; and that the air acts also injuriously upon the products of inflammation, both the consistent and fluid; changes their characters, decomposes them, and renders them more contaminating to the surrounding tissues. To prevent the injurious influence of air, it has been recommended to perform the operation under water, and while the patient is immersed in a warm bath. In certain circumstances, and more especially in the more prolonged cases, this expedient deserves attention, and even adoption.

188. Some writers have advised fluid injections into the pleural cavity, with the view of expelling both the diseased effusion and the air which may have been introduced; and it is not improbable that pure or distilled water, of the proper temperature, thus introduced, the orifice being accurately closed afterward, may have a beneficial effect, and be absorbed, although the morbid fluid was not absorbed, owing to its nature. If this measure were adopted, it should be employed in such a manner as to wash out the morbid matter as entirely as possible; and the fluid allowed to remain should not be so much as might prevent the lung from expanding, if it still possessed this power. Of the success of medicated injections in these cases, the evidence is not sufficiently conclusive. Dr. WILLIAMS states that Sir P. CRAMPTON used with success an injection of a weak solution of chloride of lime; but all stimulating injection must necessarily increase or perpetuate the inflammatory action in the surface, and thereby prove an obstacle to the expansion of the lung, and to the attainment of the end proposed by the injection, namely, the arrest of the effusion and the adhesion of the opposite surfaces. In some instances, however, the injurious effect may not result, while the beneficial effects may follow; and, therefore, such injections may be cautiously resorted to after other means have failed, and in the circumstances hereafter to be noticed (§ 189). In this state of the disease, and on occasions which the experienced physician will duly appreciate, he will agree with CELSUS in considering that the "*Anceps remedium melius est quam nullum.*"

189. In order to obtain the re-expansion of the lung, so much to be desired after the operation for empyema, and at the same time to increase the discharge of the accumulated fluid, it has been advised by LAENNEC and others to apply a cupping-glass with an exhausting syringe over the puncture. Some advantage might accrue from this expedient, if carefully performed; but it is not unattended by risk, both from injuring the lung by forcibly expanding it, and from allowing air to rush in through the opening upon removing the exhausting apparatus.

If these dangers could be sufficiently guarded against, the expedient might prove of service. The latter might be prevented, and the former could hardly be considered so great as to prevent a cautious recourse to it.

190. *D. THE COMPLICATIONS OF PLEURISY* necessarily involve the same principles of treatment as have been above developed.—(a) The most frequent complication, namely, that with *pneumonia*, forming *pleuro-pneumonia* (§ 93, 148, *et seq.*), requires very nearly the same treatment as I have recommended for either of the diseases when occurring simply, due regard being paid to the existing diathesis or states of vascular reaction and vital resistance. In this complication, however, and more especially when the sthenic character is manifest, the preparations of *antimony*, especially tartar emetic, are more frequently beneficial than in uncomplicated pleurisy; but they should be exhibited after blood-letting, and in the manner advised for pneumonia (*see LUNGS, INFLAMMATION OF*, § 96), or in conjunction with calomel and opium, as above prescribed (§ 167, 169); the other internal and external means advised for these maladies being employed as the circumstances of the case will suggest.

191. (b) When pleurisy complicates *eruptive* or *continued fevers* (§ 94), then the treatment must necessarily depend upon, 1st. The character or state of the fever; 2d. The period of the fever at which it occurs; and, 3d. The states of vital energy and vascular action characterising it. In these complications, the *asthenic* diathesis should generally be suspected, unless the character of the prevailing epidemic constitution and of the existing symptoms indicate the contrary, and the plan of cure suggested above for the asthenic or cachectic forms of pleurisy (§ 47, *et seq.*) ought therefore to be entertained, with such modification as the features of individual cases may require. It very frequently happens that the local disease is either not detected in these circumstances, or proceeds so insidiously and latently as to elude even close observation, until it has advanced far, or given rise to considerable effusion, and can admit only of the curative means which have been already recommended for the latent, the advanced, or the chronic states of the malady, as the case may be (§ 173, *et seq.*). In these complications I have seen great advantage derived from the terbinthinated epithems or embrocations, and the other external remedies mentioned above (§ 171, 175).

192. (c) The partial, adhesive, and chronic states of pleurisy which so generally complicate the advanced stages of *tubercular consumption* (§ 95) fall more legitimately under the treatment of that malady; but I may here remark, that the pleurisy which thus supervenes is not always attended by tubercular deposits, either upon the pleura or in the false membrane; although it is sometimes thus accompanied, more especially in the scrofulous diathesis, and in persons who have been exposed to depressing agents, as anxiety of mind, insufficient nourishment and clothing, and deprivation of air, exercise, and sunshine. In these circumstances, also, pericarditis may farther complicate the malady and present a tubercular character (§ 96). In both these forms of complication the friction sound is often heard on

auscultation, and then the nature of the mischief may be inferred with tolerable certainty, especially in the circumstances just stated. The treatment cannot be expected to be satisfactory in these cases, some of which are attended by either more or less anæmia or cachexia; but life may be prolonged for a very considerable period, even if it may not be saved, by a judicious recourse to chalybeate preparations, more especially to the iodide of iron with sarza, alternating this course with very minute doses of the bi-chloride of mercury, prescribed in tonic decoctions or tinctures, &c.

193. (d) In the complication of pleurisy with *hepatitis* (§ 98), and in that with *peritonitis* (§ 99, 100), the associated malady usually presents an acute character, which may pass into the chronic form if not promptly and actively treated. In these complicated states of disease, the means which are most serviceable are not materially different from those advised for the acute form of either of these uncomplicated diseases. It is generally of great importance to bring the system under the influence of mercury before effusion takes place or proceeds far; and this may be done by either the internal or the external use of the mineral, or by both modes, according to circumstances. In a case of remarkable urgency, to which I was recently called, a large blister was applied somewhat below the seat of suffering, after blood-letting was carried as far as appeared prudent; free vesication was promoted by warm poultices; and, after the cuticle was removed, the mild mercurial ointment was applied, and covered by a warm bread-and-water poultice. The most beneficial results were soon afterward observed, and the patient rapidly recovered. In these complications, the terbinthinate epithems and embrocation, advised above (§ 171), are often of great service, when judiciously employed and aided by the additional means which the state of the case will suggest.

194. In some of the complications of pleurisy just noticed, *paracentesis thoracis* can furnish only temporary relief; in others it may be most beneficial, while in a few it cannot be attempted with any sufficient prospect of advantage. It is not merely the complication which ought to be considered, but also every circumstance connected with the case, and more especially those connected with the primary malady, of which the pleuritic attack is the consequence. When this operation appears at all admissible in any of these associations, it should be resorted to as early as possible; for the several lesions mentioned above (§ 101) may soon be caused by the pressure of the effused fluid, and farther complicate a disease which an operation promptly performed might have removed.

195. *E. IN THE DARK RACES* (§ 102) pleurisy should be treated as I have advised for the asthenic and complicated forms already considered. Whether it assumes an *acute* or a *chronic* character in these races, I have always seen it more or less latent, complicated, and consecutive, more especially of tubercles of the lungs; tubercles having been found also on the surface of, or below the pleura, or in the false membranes after death (§ 102). When the effusion is great, paracentesis should be early employed. The few cases of this disease which I have seen in these races have not been so much

benefited by treatment as the natives of cold or temperate climates; but this was partly attributed to the unfavourable circumstances in which they were placed, and to the influence of a temperature and climate different from that to which they are suited by their organization.

196. *F. PLEURISY IN INFANTS AND CHILDREN* (§ 103) requires the same measures as I have advised for adults, due reference being had to age and to the susceptibility of the influence of certain remedies connected with infancy. In this class of subjects, pleurisy is most frequently consecutive and complicated, and the treatment should be prescribed accordingly. For very young children especially, some remedies which are most beneficial for adults with this disease should either not be employed at all, or with great caution. The chief of these are opium and other narcotics, tartar emetic, and blisters; but calomel may be given freely without risk, with small doses of JAMES'S powder, vascular depletions being promptly employed, and to an extent which the circumstances of the case will warrant. The terebinthinate epithem or embrocation will prove of great service, and will be attended by no risk, unless the utmost neglect be evinced. If the application of a blister be considered advisable, with the view of obtaining a discharge from the external parietes of the chest, it should not be continued longer than three or four hours, or until slight redness of the surface is caused by it, when a warm bread-and-water poultice should be applied, which will usually produce vesication without subsequent risk, if due attention be paid to the case.

197. In the acute stage of the malady, the treatment now advised, aided by diaphoretics and diuretics, should mainly be trusted to; but, as the chronic stage advances, and particularly as effusion increases, the iodide of potassium may be prescribed, with liquor potassæ and some preparation of sarza, or with the addition also of a diuretic; the terebinthinate liniment, or a liniment containing the iodine of lead, or iodine of potassium, being occasionally applied to the side, or the emplastrum ammoniaci cum hydrargyro, or equal parts of this plaster and of the emplastrum picis comp. If the patient evince a marked debility, or cachexia, anæmia, or constitutional vice in the chronic stage, the iodide of iron should be given in the sirup of sarza, and change of air, especially to the sea-side, be recommended; the external applications just mentioned, or the frequent sponging of the surface with warm salt-water, or with a tolerably strong solution of bay-salt in warm water, or the use of these alternately, being also resorted to. If effusion be considerable, especially if the patient live in a large town, change of air to the country, aided by suitable alterative and diuretic medicine, will generally remove the disease, unless it have become complicated, or the vital powers be very depressed, and the constitution cachectic.

198. Treatment, judiciously directed, is generally much more efficacious in this class of patients than in persons advanced in age, or even in adults; and the more serious consequences of the disease, as empyema, with or without fistulous opening, should not be considered hopeless, unless complicated disorganization exists. Whenever the effusion appears to be

puriform, no delay in resorting to paracentesis thoracis should take place in children, more than in adults; and in the former especially, it is hardly ever too late to perform this operation, particularly when the effusion is of this kind.

199. iii. *DIET AND REGIMEN.*—It is almost unnecessary to add anything on this topic, as it must be evident that both the diet and the regimen should be strictly antiphlogistic during the acute stage, more especially when the disease presents a sthenic character. As effusion advances, or becomes chronic, and especially if vital resistance be weak, it will often be necessary to support the powers of life with such means as will the least excite vascular action or accelerate respiration, and at the same time tend to increase the natural secretions and excretions. This becomes the more requisite in the scrofulous diathesis, or when the effusion is puriform, and attempts to discharge and prevent the return of the effusion are being made. But there is no aid to a judicious treatment that deserves more general adoption than change of climate, especially to the sea-side, to a mild air, and to a dry situation. A person who is recovering from pleurisy should guard, both during convalescence and for a long time afterward, against currents of cold air; against wet, cold, or damp feet; and against errors in diet; and he ought more especially to avoid standing upon cold stones, or floor-cloth, or in damp places. His shoes ought also to be changed after walking, immediately upon returning home.

200. XII. *STRUCTURAL CHANGES OF THE PLEURA NOT NECESSARILY ARISING FROM INFLAMMATION.*

CLASSIF.—IV. CLASS. II. ORDER. (*Author in Preface.*)

1. *DEFIN.*—*Lesions of the pleura not necessarily depending upon, although frequently associated with, inflammatory action, but often arising from diathesis, or constitutional vice or contamination, and seldom attended by distinct signs, although their presence sometimes may be inferred from the history of the case, and from various local and general symptoms.*

201. i. *DESCRIPTION.*—I have so fully described those lesions of the pleura resulting from inflammation (§ 112, *et seq.*), that I cannot farther advert to them than to briefly notice some of their associations with those alterations about to be considered. Certain lesions which I shall point out doubtless originate, in most cases, if not in all, in inflammatory action; but they subsequently undergo changes, which may be referred to morbid nutrition, this nutrition giving rise either to a transformation of the tissue to one of a different nature; to the transition of this tissue to another different from it, but not foreign to the economy, or to the production of a structure altogether adventitious to the healthy frame. It is thus that we perceive, as a consequence of pleuritis, and owing to the states and grades of action, and to the conditions of the constitution, cartilaginous or ossific deposits or transformations of the pleura in some cases; and, in the course of this disease, owing to constitutional vice, tubercular deposits either beneath the pleura, or in the albuminous or fibrinous deposits, or false membranes on the free surface of this membrane. The former le-

sions most probably originate in inflammatory action or irritation, the morbid nutrition proceeding as this action subsides; but the latter lesion is either coetaneous with the inflammation, or excites it, or is a consequence of it, in the scrofulous or tubercular diathesis. The lesions more immediately as well as remotely consequent upon inflammation of the pleura have been described above (§ 112, *et seq.*), with the exception of *gangrene, ulceration, and perforation* of this membrane, of which I proceed to take farther notice.

202. *A. Gangrene of the pleura* occurs only on very rare occasions, and chiefly as a consequence of either gangrene of the subjacent lung, or abscess of this organ, or external to the costal pleura. A sphacelated state of the pleura may also occur in an advanced stage of chronic pleurisy or empyema in the form of gangrenous ulcers, as remarked by LAENNEC, BARON, and CHOMEL, but this is very rare. Gangrene of the pleura is generally limited to a small space, and presents the appearances of irregular patches of a brownish green, livid, or very dark hue, that softens, ulcerates, and passes into a dark-grayish, dirty, and irregular surface, exhaling a fetid odour. Around these patches, indications of inflammatory action, with certain of the more usual consequences of this action, are generally observed.

203. *B. Ulceration and perforation of the pleura* are not infrequently met with, and are noticed, especially as regards their chief consequences, under the head of chronic pleurisy, and in the article PNEUMATHORAX. They may take place under a variety of circumstances, especially when they commence, as more frequently is the case, in the attacked surface of the pleura, perforation proceeding from this surface inward. In cases of abscess, or of tubercular softening and ulceration, or of gangrene of a superficial portion of the lung, softening and ulceration of the pleura covering this portion thus supervene, and sometimes go on to perforation. Hæmorrhage from injury or disease of a blood-vessel, or pulmonary apoplexy, may cause rupture of the pleura at the nearest point to the seat of effusion. Either ulceration or perforation, or rupture of the pleura, may likewise be caused by abscess seated in some place external to this membrane, as an abscess of the lungs, liver, &c.; or by hydatids, cysts, tumours, aneurisms, and injuries of any adjoining structure or part. In all these circumstances the perforation commences in the attacked surface, and advances into the pleural cavity; but it may proceed from within outward; but this is very rarely the case unless in general or partial empyema, when the matter is evacuated either through the lungs or at some part of the thoracic parietes, as already described (§ 87-92).

204. *C. Effusions into the Cavity of the Pleura.*—Those which depend chiefly on inflammatory action have been described above (§ 115, *et seq.*), and have been shown to consist of serous, sero-albuminous, or plastic products, which may undergo various changes of puriform matter, and more rarely of a sanguineous or sero-sanguineous fluid. Those which take place independently of inflammation are simple serous or watery effusive hæmorrhages, and the passage, owing generally to perforation or rupture of the pleura, of gaseous fluids, or of purulent, gan-

grenous, tuberculous, or cancerous matters into the cavity.

205. *(a) Watery effusions, or passive serous effusions,* require no farther notice than they have already received when treating of *dropsy* of the pleural cavity, they being usually independent of disease of the pleura itself (*see art. Dropsy*, § 158, *et seq.*).

206. *(b) Hæmorrhagic effusions* into this cavity, or *hæmorrhage*, may proceed from a hæmorrhagic form of inflammatory action implicating this membrane, characterized by deficient vital powers and a morbid state of the blood itself; or from loss of tone of this surface and of the capillaries ramified to it; or from this state conjoined with an hæmorrhagic tendency, or from rupture of an aneurism, or injury or disease of some vessel adjoining or involving the pleura. In the former states, the effusion, whether altogether sanguineous, which is very rarely the case, or sanguineo-serous, is an exudation from a greater or less extent of the pleural surface, this surface being more or less concerned in causing the effusion. In the latter this surface is generally healthy, the blood-vessels subjacent or adjoining it being principally affected. When blood is effused into the cavity of the pleura, inflammation is usually thereby produced; and generally with a rapidity according to the quantity and purity of the blood effused, the resulting phenomena varying with the condition of the patient and circumstances in which he is placed.

207. *(c) The effusion of gaseous fluids* into the cavity of the pleura is considered in the article PNEUMATHORAX, and of *purulent collections* I have already treated. *Tubercular and cancerous productions* often form within the pleura, but they also appear external to it, as well as involve its structure, as will be shown in the sequel. The passage of gangrenous, carious, ichorous, or other morbid products, from disorganization of an adjoining part into the cavity of the pleura, may likewise occur in the manner already stated; but, when this takes place, inflammation is thereby rapidly exerted throughout the serous surface. Simple *cysts* and *hydatids* are rarely or never formed within the pleural cavity, and are rarely developed externally to it, or, at least, in such situations as allow them to find their way into this cavity.

208. *D. Cartilaginous and osseous formations,* or transformations of the pleura, are not very rarely met with. In some instances these changes appear to exist immediately under or external to the pleura, or on its attacked surface, the membrane retaining its natural structure and polished surface. In others they seem more entirely to involve the pleura, as if arising from thickening and induration of this tissue, and advancing through the fibro-cartilaginous state to osseous transformation; and in some cases they are confined entirely, or in part, to the false membranes or adhesions formed on or between the pleural surfaces. They evidently result, as noticed above (§ 201), from a state of chronic inflammation or irritation that has passed into morbid nutrition, the fibro-cartilaginous condition being intermediate between simple thickening with induration and ossification. They have been found of various grades of thickness, from a line or two to an inch, and seated in or upon either the costal, the dia-

phragmatic, or the pulmonary pleura, and in some cases in the false membranes existing between and connecting these. In some instances the transformation is neither altogether cartilaginous nor entirely osseous, bony matter, in lamellæ, or in irregular forms, and in detached patches, existing between the layers of cartilage, or otherwise irregularly deposited.

209. These productions are found either in the form of smooth plates or lamellæ, or in that of irregular nodules, or they present a rough surface, with irregular acuminations or points. They are never met with to any considerable extent in connexion with the pulmonary pleura, without the subjacent lung being more or less consolidated. In rare instances, they have assumed a rounded, oval, or globular form, either with bases of varying sizes, or with narrow and short peduncles, their surfaces being smooth and shining, as if still covered by the pleura. These nodules may be single, or several may exist in the same case, their magnitude varying from that of a pea to that of a large cherry.

210. *E. Fatty appendages* have been found attached to the free surface of the pleura, but very rarely, at least entirely unconnected with adhesions between the opposite surfaces. I have met with these appendages in several cases, but in all they appear to have been developed by the formation of fat underneath a portion of false membrane, and between it and the pleura, the false membrane having been of old date. In some cases, old adhesions, having a polished serous surface, and a thick or rounded form, have consisted, excepting their surfaces, entirely of fat.

211. *F. Tubercles* may be formed either on the attached surfaces of the pleura in the subserous cellular tissue, or in the pleural cavity. In the former situation they chiefly consist of numerous small granulations under the pulmonary pleura; and sometimes they form more considerable masses developed beneath the costal pleura, and causing elevations of the pleural surface. Tubercles are never found within the pleural cavity, unless in connexion with false membranes or adhesions, and infiltrating or studding these, as described above (§ 120), thus constituting the *tubercular form of pleurisy*. But they may exist in both situations in the same case, as well as in the lungs and adjoining membranes, as the pericardium, peritoneum, &c. Tubercles may be formed underneath or upon the attached surface of the pleura; as just described, and may advance even farther in their development without any evidence of inflammatory action in their seats or vicinity. But the circumstance of their constant coexistence with certain of the products of inflammation, when they are found within the pleural cavity, or upon the free or internal surface of the pleura, suggests the question, whether they are the *cause* or the *result* of inflammation in the tubercular diathesis. That they are merely one of the products of inflammation in this diathesis, are excluded, in a rudimental state, with the lymph produced by the inflammation, and are further developed as the organization and other changes of that lymph advance, are circumstances rendered probable by their constant coexistence with these products; while the opposite doctrine, that they are the causes of the inflammation,

and of the consequent exudation of lymph in which they are enveloped, necessarily allows that they are first thrown out or formed upon the free serous surface, where they excite the irritation and inflammation, with its consequences found in connexion with them. Now if they are thus formed on the free serous surface, before inflammation is developed, it is reasonable to infer that they should be found, in some instances, before this effect is produced, or produced to an extent rendering the cause doubtful; but this has hitherto not been remarked (*see* § 120).

212. *G. The several forms of malignant or cancerous degenerations* have been observed involving the pleura, but generally consecutively, never primarily. These lesions, whether schirrous, carcinomatous, encephaloid, or fungo-hæmatoid, when they implicate the pleura, are consequent upon their existence in some other part of the economy, most frequently in the mamma, in the axillary glands, or in some other situation in the vicinity. They first extend to the subjacent cellular tissue, causing an irregular thickening and induration, with their characteristic forms of degeneration of this tissue, and an irregularity or unevenness of the serous surface, which ultimately becomes variously changed in color and consistence, according to the form and progress of the malady, until it altogether loses its natural hue, and is altogether involved in the malignant structure. At this advanced stage the surface and cavity of the pleura generally present more or less of a turbid, dirty, ichorous, or sero-sanguineous fluid, which is sometimes also offensive, or of a peculiar odour.

313. ii. SYMPTOMS AND SIGNS OF STRUCTURAL CHANGE OF THE PLEURA.—The *symptoms* and *signs* of these changes are mostly the same as have been described above as indicating the progress and advanced stages of inflammation of this membrane. Those changes, which are essentially the result of inflammation, most necessarily present these symptoms and signs which, in connexion with the history of the case, usually show the nature, if not always the exact extent, of the disease. But those lesions which consist of adventitious formations, as regards either the situation or the economy, frequently advance without any distinct symptom or sign from which their existence may be inferred.

214. (*a*) *Gangrene of the pleura* (§ 202) being met with chiefly as a consequence of gangrene of a portion of the lung, is preceded by the indications of this occurrence. When the symptoms of gangrene of the lungs (*see* LUNGS, § 173–175) are followed by an acute pain in the side, painful cough and inspiration, extreme anxiety and depression, followed generally by all the usual symptoms of the utmost vital exhaustion, then this lesion may be inferred. The physical signs may consist merely of dulness in percussion, of greater or less extent, with absence of the respiratory sound.

215. (*b*) *Ulceration of the pleura* (§ 203) is announced only when it has terminated in *perforation*. If the ulceration has proceeded from the attached surface into the cavity of the pleura, the passage of the matters, whether gangrenous, puriform, tuberculous, æriform, &c., the patient very suddenly experiences

acute pain in the side, with oppression, dyspnoea, and anxiety; and if air passes rapidly into the pleural cavity, these latter symptoms are not only sudden, but also extreme, and are attended by the physical signs of *pneumothorax*. When ulceration, followed by perforation, takes an opposite course, proceeding from the internal cavity externally, as stated above (§ 203), then the symptoms already described (§ 87, *et seq.*) as attending *empyema*, when terminating in this way, are usually observed.

216. (c) *Acute or inflammatory effusions into the pleural cavity* have been already fully noticed (§ 204–207) as respects the symptoms and signs they produce, and passive effusions into this cavity have been elsewhere treated of (*see art. Dropsy*, § 158, *et seq.*). Effusion of blood into this cavity, *hæmorrhax*, unless when it occurs from rupture of an aneurism, or from external injury, is a rare occurrence, as shown when treating of hæmorrhage into the pleural cavity (*see art. Hæmorrhage*, § 277). As a pure exudation in this situation, it is very rarely met with, although the exhalation of a greater or less proportion of red particles with the serum of the blood, in some extreme cases of asthenic acute pleurisy, or of cachectic pleurisy, is not very infrequent, and constitutes the *hæmorrhagic pleurisy* of LAENNEC. *Hæmorrhax*—or the effusion of blood into the pleural cavity, analogous to the hæmorrhages, active or passive, of other organs or surfaces—is so rare, that the phenomena attending or consequent upon it have not been satisfactorily observed, and they are hence imperfectly described. But, whether the blood poured out in this situation be a primary lesion, or consecutive of some other, or of local injury, I cannot view it, with M. LAENNEC, as an occurrence devoid of importance, as regards its effects upon the pleural cavity, or believe that the blood effused in this situation will be absorbed without producing inflammation in this cavity. My experience has proved that, although absorption does take place, inflammatory action, varying in character and intensity with the circumstances of the patient, is the most frequent result, as I have already shown (§ 206). It must be admitted that effusion of blood into the pleura will produce similar symptoms to those resulting from other effusions to the same amount. But it will be generally observed that indications—either local or constitutional, or both—of inflammatory action of the pleura will sooner or later supervene; and that the products of this inflammation, mingled with altered and nearly absorbed blood in the pleural cavity, will give rise to peculiar appearances, on examination after death, more distinctive of the immediately antecedent inflammation, than of the hæmorrhage which developed the inflammation. I have nothing to add at this place to what I have stated above respecting the symptoms and signs of purulent or of other effusion into the pleura (§ 63, *et seq.*), and have advanced in the *art. PNEUMOTHORAX*, when noticing the combination of æriform and fluid effusions into this cavity.

217. (d) *Cartilaginous and ossific formations* in the pleura are not indicated by symptoms or signs during life. They are merely contingent changes, occurring after chronic pleurisy, and are met with chiefly in persons who have lived

for a considerable time after such attacks, with more or less disorder of the respiratory functions, and probably with dulness on percussion, or with imperfect or absent respiratory murmur; and although their existence may possibly be in some instances suspected during life, they are unattended by any peculiar symptom or indication.

218. (e) *Tubercles* formed immediately beneath the pleura, occasioning small or irregular elevations of the membrane (§ 211), without much effusion, are generally attended by a rubbing sound during respiration; but if effusion exist, or if the tubercles be deposited in false membranes, their presence can be suspected only, and chiefly from the coexistence of the pleuritic lesion with tubercular consumption, or from the occurrence of this lesion in the scrofulous diathesis. Tubercular formations are most frequently found in one side only, in the same case, but they may exist in both cavities; and they may be present in both the pleura and in the pericardium. When this latter complication occurs, without much effusion within the pericardium, there is generally a cardiac rubbing sound in connexion with a similar sound during respiration.

219. (f) *Cancerous or malignant alterations* in the pleura may be inferred from the gradual, nearly latent, and chronic or sub-acute form, in which the pleuritic affection supervenes upon malignant diseases of the mamma, or in the vicinity of the thorax; and from the presence of symptoms and physical signs similar to those attending tubercular formations in this membrane. The rubbing sound generally continues for a considerable period, and until the subsequent effusion becomes copious; and the pleuritic symptoms appear chiefly when the cachexia attending the cancerous malady is well marked, and the system manifests more or less of the usual accompanying anæmia.

220. iii. *TREATMENT*.—The treatment of the organic lesions of the pleura now passed under review, should be directed entirely by the circumstances of the case, and by the evidence furnished of their individual existence, and of their morbid associations.—(a) If there be reason to infer the supervention of *gangrene* of this membrane, treatment is then very rarely of any farther avail than to prolong existence for a few hours, or at most a day or two; and this object can be attained only by the exhibition of restoratives, &c., as camphor, ammonia, quinine, myrrh, ammoniacum, &c.; for, although recovery from gangrene of the substance of the lungs may take place by the aid of these or similar means, it is very rarely procured when this lesion has extended to the pleura.

221. (b) As to the treatment of *ulceration and perforation*, of, and *effusions* into, the pleura, I can add nothing to what I have recommended to be done for the more advanced stages, and more chronic forms of pleurisy (§ 63, *et seq.*), for which, however, and more especially for the more simple states of effusion, the means there advised, when judiciously administered, will be often very successfully employed, especially when aided by a free use of the acetate of potash, so as to act manifestly both upon the bowels and kidneys; and by the external means above mentioned (§ 175, *et seq.*). If the causes and circumstances of the disease lead to the

inference that much blood is effused into the pleural cavity, or that this fluid constitutes the larger part of the effusion, I believe that the operation for empyema should not be delayed, otherwise inflammation, if it have not already appeared, will certainly supervene, in a form not readily removed by treatment, inasmuch as the blood, or at least its unabsorbed portion, will remain to perpetuate the disease, and favour the occurrence of consecutive lesions.

222. (c) The treatment of the other organic lesions of the pleura promises but few advantages when their presence are even presumed. *Tubercles* are very rarely present in this membrane, without existing in still greater abundance, and often in advanced states, in the lungs or other structures. Hence the treatment requires to be directed in many cases more to these organs than to this special lesion; and, even when the features of the case warrant the direction of remedies principally to this seat of disease, it will be difficult to suggest others more likely to be beneficial than those advised above for chronic pleurisy (§ 175–179). The *mistura ferri composita*, the iodide of potassium, the iodide of iron, the liquor potassæ with tonic infusions and sarsaparilla, or these variously combined, or conjoined with such other substances as the peculiar circumstances of the case will suggest, are most generally appropriate for these lesions, as well as for the effusions into the pleural cavity, by which these lesions are often attended, especially when aided by suitable means for the promotion of the alimentary and renal evacuations, and by external derivatives.

PLEURODYNIA.—SYNON. *Pleuralgia*, *Pleurodynia* (from πλευρά, the side, and δόνην, pain)

*Pleuritis spuria, pseudo-pleuritis. Neuralgia thoracica, Pleurodyne*, Auct. Var. *Dolor lateris. Rheumatismus Pectoris*, Naumann. *Pleurodynie, Point de Côte, Fausse Pleurésie*, Fr. *Der Seitenschmerz, der falsche Seitenschick*, Ger.

CLASSIF.—I. CLASS, IV. ORDER (Author).

1. DEFIN.—Pain in the side, usually occurring and ceasing suddenly, independently of any physical sign of inflammation of the pleura, and generally connected with rheumatic, neuralgic, or hysterical affection.

2. *Pleurodynia* and *pleuralgia* are names in no way applicable to the painful affection under consideration, inasmuch as there is no evidence in favour of the pleura being at all implicated in it, unless it change its nature, or superinduce or pass into pleurisy. If, however, the word *πλευρα* be viewed, as it was by the ancients, as meaning the side, without reference to any particular part or structure of the side, these terms will appear much less objectionable. That this affection is not always rheumatism of the chest, as implied in the name given to it by NAUMANN, is a fact which experience will soon teach the inexperienced. Nor should it be viewed, as it has been by M. JOLLY and others, as inflammation of one or more of the muscles of the thorax. But it is often connected with rheumatism, either in some other part of the body, or with the rheumatic diathesis; and it may be converted or pass into inflammation of the pleura, or of the pericardium, owing either to the predisposition and constitution of the patient, or to injudicious treatment. When it thus presents a rheumatic character, then it is to be viewed and treated as I have advised in the article RHEUMATISM, although it is by no means demonstrated, however frequently it has been assumed, that the pain constituting the principal feature of the disorder is caused by an affection of the intercostal muscles, or of the fibrous fascia lining the chest.

3. I. CAUSES.—Persons of a nervous, susceptible, or irritable temperament; of the rheumatic and hysterical diathesis; those who are exposed to atmospheric vicissitudes, to currents of cold air, to marshy or humid exhalations, or to cold or wet in any way, and those who live in damp, cold, and low houses, or in cellars, &c., are the most liable to experience those rheumatic and neuralgic affections in the side which have generally received the name of *pleurodynia*. Owing to the greater exposure of males than females to these causes, the former are most liable to them; and adults and aged persons are more frequently affected than children and young persons. But all the causes of inordinate excitement, and of exhaustion or direct depression of the nervous system, both predispose to, and more immediately occasion, painful affections, in either side, as well as in other parts of the body. Owing to the prevalence of the above causes, especially those which proceed from season, climate, and the soil and water of a locality, pleuralgic affections may be so prevalent as to be *endemic*, but they can rarely be considered as epidemic, or as being so generally prevalent, even in those localities, as to deserve that character.

4. II. DESCRIPTION.—*Pleurodynia* varies much in character with the causes which produce it, and according as it occurs in a *rheumatic, neuralgic*, or *hysterical* diathesis, or presents either

of these forms.—(a) In the first of these forms, it may be either acute or chronic; in the former it is sudden, severe, lancinating, increased upon pressure, even upon the slightest pressure or contraction of the affected muscles. It often ceases as suddenly as it appeared, the pain shifting, or having shifted, to some other part. This more acute state of the affection is frequently attended by more or less fever, and the other phenomena of acute rheumatism. The chronic state is generally prolonged for many days, sometimes subsiding altogether for a time, and then suddenly recurring either in the same place, or in the vicinity. It occasionally ceases during the day, and recurs at night; or it disappears when warm in bed, to return at some period of the day. The pain is exacerbated during respiration; but this may take place either during inspiration or expiration only or chiefly, according as the muscles and nerves supplying be inspiratory or expiratory. Coughing, sneezing, and all movements which affect the muscles, occasion a sharp or cutting pain of the part.

5. (b) The *hysterical* and *neuralgic* forms of *pleurodynia* are more manifestly seated in the sentient nerves than the rheumatic, and are referred chiefly to some part between the sternum and spine. They are often connected with irritation about the origin of the dorsal nerves, or in the ganglionated roots of these nerves; this irritation, whether functional or inflammatory, being either seated there, or reflected thence from the renal or sexual ganglia, or nerves, or from the uterus and ovaria. These forms of *pleurodynia* are much more frequent in adult females than in males; in the nervous and irritable temperament; in persons who are subjects of *anæmia*, or who are liable to irregular determinations or distributions of blood; and in those especially about the period of the catamenia, and when this discharge is irregular, difficult, scanty, or interrupted. (See art. HYSTERIA, § 78, *et seq.*, and NEURALGIA, § 89, *et seq.*)

6. (c) Occasionally cases occur in which the pain cannot be referred either to rheumatism or to any neuralgic or hysterical condition, but rather to disorder of some one of the *digestive viscera*; to either the stomach, the duodenum, the colon, or the liver. In these cases *flatulence* is a very prominent symptom, the *pleurodynia* being entirely sympathetic of the distention or irritation caused by the flatus contained in one or more of these viscera. But, in addition to this symptom, other indications of disorder of the digestive organs are usually present, especially a loaded tongue, the edges being red or flabby; an irregular and flatulent state of the bowels; and an unhealthy condition of the secretions and excretions. These symptoms are, however, often present in the other forms of *pleurodynia*, but they exist in this generally in a very prominent manner, and without any evidence of rheumatism, or of hysteria having been previously complained of.

7. III. THE DIAGNOSIS OF *pleurodynia* rests upon, 1st, the phenomena immediately connected with the painful affection; and, 2d, the absence of the symptoms and physical signs of pleuritic, pericardiac, and pulmonary disease. If *pleurodynia* occur in connexion with rheumatism or in the rheumatic diathesis, or if the patient be subject to any form of hysterical af-

fection, or furnish any indication of spinal irritation, or be liable to disorder of the catamenial discharge, then it may be suspected that the pain is independent of inflammation of the pleura or lungs; but the suspicion can be confirmed only by a careful examination of the chest by percussion and auscultation, and by the absence of the physical signs attending inflammatory or structural diseases of the thoracic viscera. The negative evidence thus furnished, the absence of many of the rational symptoms of these diseases, the manifest nervous, or rheumatic, or dyspeptic character of the affection, and the several causes or circumstances which appear to have produced it, will generally guide the careful observer to a correct conclusion as to its nature and morbid relations.

8. IV. The TREATMENT should depend upon the conclusion thus arrived at. If the affection be manifestly rheumatic, the treatment advised for RHEUMATISM is required; and if the patient be young, robust, plethoric, &c., a moderate bleeding from the arm, or the application of leeches to the side, may precede other remedies. When the pain seems to depend upon disorder of the digestive organs, or upon biliary or other colluvies, then a suitable but smart emetic, followed, after an interval, by cholagogue aperients, by a warm bath, and by diaphoretics, will generally remove it. As this affection is merely the manifestation of a disorder seated more internally or deeply, the suppression of it by external applications should be avoided until the primary affection is removed by a treatment directed to it entirely or chiefly; and when all disordered secretions and excretions are removed, and when the functions and tone of the digestive organs are restored, then whatever of painful affection may remain may be treated by rubefacient and anodyne embrocations or applications, by tonics, and the other means advised for NEURALGIA. The treatment should in every respect be directed conformably with the morbid relations which the case may present. The very general connexion existing, in females, between this affection and disorder of the catamenia requires that treatment should be more especially directed to the removal of that disorder. In this form of the affection, as well as in every other, the intentions and means of cure should have for their objects the precise origin of this and of its associated evils, and the removal of the source of them just adverted to; for as long as it exists the symptomatic effects will recur again and again, or whenever circumstances favour their evolution.

PNEUMATHORAX.—SYNON. *Pneumothorax*, Itard. *Pneumathorax* (from Πνεῦμα, air, and θώραξ, the chest). *Pneumatothorax*; *die Luftbrust*, Germ. *Pneumothorax*, Fr.

CLASSIF.—IV. CLASS, II. ORDER (see Preface).

1. DEFIN.—*The presence of air in the pleural cavity, occasioning collapse or compression of the lung, extreme dyspnoea and anxiety, and obvious physical phenomena.*

2. I. PATHOLOGY OF.—Pneumathorax is the

consequence of lesions, generally of both the lungs and the pleura, or rather of the lung implicating the pleura, allowing the irruption of air into the pleural cavity, and thereby suddenly occasioning severe circumscribed pain in one side, great anxiety, and extreme dyspnoea. It may occur at any period of the course of phthisis; and, as in one case in my practice, it may even take place before the patient has complained, or had recourse to medical aid. This dangerous and generally fatal result of pulmonary tubercles has attracted attention only in modern times. It is usually developed as follows:

3. (a) A tubercular cavity may extend to the pleura, inflame, and ultimately perforate this membrane, before adhesions have formed between the opposite surfaces, and thus the air will pass into the cavity of the pleura. This is the most common way in which pneumathorax occurs.—(b) One or more tubercles may form so close to the pleura as to perforate this membrane, and open into a minute bronchus, in the course of softening, even at an early period of the pulmonary disease, and without having produced a limited inflammation of the pleura, or adhesion of the opposite surfaces, at least in a sufficient degree to prevent the passage of air into the cavity of the pleura. This, however, does not occur so frequently as the former; yet I have met with two cases.—(c) In the course of partial pleurisy, the absorption of the contained fluid may leave a void, which is not occupied either by a contraction of the parietes of the chest or by the lung, which continues either condensed, or bound down by adhesions or false membranes. This vacuum, which may be either very small or more considerable, contains air secreted by the surfaces, by which the fluid was absorbed. Dr. WILLIAMS mentions two cases of this kind; but this is a rare form of pneumathorax.—(d) It has been supposed that the products of pleurisy may undergo such changes as will develop a gaseous fluid, especially in the more cachectic states of the disease, and at an advanced period, or shortly before death. Without denying the possibility of this occurrence before death, it may be admitted to take place, in some instances, soon after death. There is not, however, sufficient evidence of this change in the effused fluids in pleurisy having supervened during life to allow of its being ranked as a variety of pneumathorax.—(e) Air may also be present in the cavity of the pleura, owing to a fistulous opening through the parietes of the chest, or in consequence of a fistulous communication between this cavity and the bronchi on the one hand, and the external surface on the other.

4. The intimate adhesions which usually form between the pleura covering the tuberculated portion of lung and the costal pleura obviate the occurrence of pneumathorax; yet when these adhesions either do not take place, or when they are either incomplete or not intimate, and the softened tubercles or the extending ulceration perforates the pleura, then the air passes into the cavity, distends it, compresses the lung, and gives rise to the symptoms and physical signs of this organic mischief. Most frequently the resulting perforations are small, consisting of an oval aperture, or small fissure, three or four lines long, frequently in

the midst of a soft, dirty, grayish, or yellowish texture, which is easily torn. There is usually only one perforation; but several in the same case have sometimes been met with. The perforation occurs in about five sixths of the cases near the angles of the third or fourth ribs; that is, in a place corresponding with that where pain was felt, and where pleuritic adhesions, when not general, commonly terminate. In other cases it is more or less distant from the apex of the lung; but it very rarely takes place at the apex, owing to the frequency of adhesions in this situation.

5. Perforation of the pleura, occasioning pneumothorax, is much more frequent on the left than on the right side. This is probably owing to the somewhat more frequent occurrence, and the more advanced progress, of tubercular ulceration in the left than in the right lung. Dr. REYNAUD found, in forty cases of perforation, ascertained by post-mortem examination, that this lesion was twenty-seven times on the left side, and thirteen times on the right; and in ten similar cases, not demonstrated by examination after death, the left side was affected in six cases, and the right in four. Dr. HASSE met with pneumothorax nine times on the left and seven times on the right side. M. LOUIS observed this lesion seven times on the left side, out of the first eight cases which occurred to him.

6. The perforation generally depends upon the progress of ulceration, usually tubercular, very rarely gangrenous, through the pleura. In ordinary circumstances, when ulceration approaches the pleura, inflammation, with the exudation of plastic lymph, supervenes at that part of this membrane which is nearest the ulcerated cavity, and protects that part of it, either by covering it with a thick false membrane, or by uniting it to the opposite surface by this medium. If a firm adhesion of the surfaces has formed, and the ulceration proceeds, perforation of both the pleura and the false membrane takes place without being followed by pneumothorax; and even the parietes of the chest may ultimately be perforated, the adhesions of the pleural surfaces around the fistulous perforation preventing the air from passing into the cavity of the pleura. But in other cases, especially when either vital power and resistance are weak, or the lymph thrown out is of an unhealthy or unorganizable character, and hence neither false membranes nor intimate adhesions are formed, or are not formed in a state sufficient to protect the ulcerated surface, the air passes into the cavity of the pleura, at one or more points, upon sudden efforts, or severe fits of cough. Ulceration may advance until the pleura is nearly perforated, either without the production of a false membrane or of adhesion, or with these in a more or less incomplete state, when a severe fit of coughing, or a forced inspiration, or some effort, or even an external injury, causes the thinned or ulcerated point to give way suddenly, and induces all the symptoms and signs of pneumothorax.

7. II. SYMPTOMS AND SIGNS.—A. SYMPTOMS.—The effects of the perforation are *immediate* and *consecutive*.—(a) The *immediate effect* is to admit air more or less rapidly into the cavity of the pleura, which permits the lung to as-

sume that state of collapse to which its natural contractile property would reduce it, by equalizing the atmospheric pressure within and without it. In addition to the introduction of air and the dyspnoea thus rapidly produced, the sensibility of the part is generally also suddenly and severely excited, and, with the extreme dyspnoea and pain, great anxiety is felt. The connexion between the lesions and the symptoms is remarkably striking. The pain corresponds with the rupture of the thinned portion of pleura and the irruption of the tuberculous matter into the pleura, and is caused by these occurrences; while the threatened suffocation and anxiety are the effects of the rapid passage of air and of some fluid matter into the pleural cavity. Therefore, when acute pain, oppressed breathing, extreme anxiety, and the symptoms of acute pleurisy display themselves *suddenly* in one side of the chest of a tubercular or phthisical patient, we may suspect the occurrence of perforation of the pleura, and ascertain the presence of pneumothorax by examining the chest.

8. (b) The *consecutive effects* of perforation vary in different cases. Although perforation of the pleura will not fail to allow air to pass into the cavity, yet the size and other conditions of the opening modify the amount of air introduced and the effects which follow. If the perforation be very small, or if it be so placed that the walls of the chest close it upon expiration, or if it be below the level of the effused fluid, or if the opening be of such a form as to become valvular, and to close the aperture on expiration, air will pass into the cavity in accumulating quantity, and occasion an increased compression of the lung; and even suffocation in the course of a few hours, and before many of the consequences observed, in cases of longer duration, can take place. When, however, the termination of the mischief is not so rapid, the presence of air in a cavity neither accustomed to, nor organized for it, and of the matters which pass along with the air from the ulcerated cavity, excite with more or less rapidity great irritation and inflammation of the pleura, attended by acute pain, dry cough, dyspnoea, spasms of the intercostal muscles; quick, weak, or irregular pulse; heat of skin, and all the symptoms of acute pleurisy, with the physical signs of pneumothorax (§ 11), and of liquid effusion accompanying the air contained in the pleural sac.

9. When the aperture, by which air passes into the cavity of the pleura, is large, there is a frequent renewal of the air in this cavity; for the lung is kept in a state merely of collapse, and not of forcible compression; the air passing out of the cavity, as well as passing in, to a partial amount. The consequences are, a more copious purulent secretion takes place from the pleural surface, and this secretion always becomes more or less fetid if it continue for some time. The foregoing symptoms, however, are not of themselves sufficient to show the existence of pneumothorax; for, notwithstanding the sudden supervention of acute pain in the side, with oppressive dyspnoea and anxiety, and although, in some instances, these symptoms may be instantly felt after a fit of coughing, or upon exertion when the patient has felt as if something had given way in the

pained place, still all these phenomena may exist in some acute cases of pleurisy, without any perforation; while, on the other hand, perforation and pneumathorax may take place without any very acute or suddenly developed symptoms, although this is seldom observed. The physical signs, therefore, are chiefly to be depended upon for the diagnosis of this lesion.

10. When the quantity of air which is passed into the pleural cavity is great, if there be no adhesions between the opposite surfaces of the pleura, or if these adhesions be inconsiderable or admit of being much stretched, the lung is compressed and forced against or towards the spinal column. At the same time, the thoracic parietes on the affected side are distended, the ribs separated, the diaphragm depressed, and the mediastinum pushed to the opposite side. The widening of the intercostal spaces, the rounding and dilatation of the parietes, the much less degree of motion during respiration, and the much greater dimensions of the affected side upon admeasurement, sufficiently indicate the distention of the pleural cavity by the accumulation of a fluid; the nature of the fluid, whether gaseous or liquid, being readily indicated by the physical signs. The viscera are also displaced by the contained air. The heart and mediastinum are pushed to the right side, if the left be the seat of lesion; and towards the left axilla, if the right is so affected, and if the air be in great quantity, while the liver and stomach are pushed downward; the upper regions of the abdomen sometimes protruding more or less.

11. *B. THE PHYSICAL SIGNS* are the most important of the *consecutive effects* of pneumathorax, and are generally very distinctive. The air contained in the pleural cavity gives the walls of the chest a greater degree of resonance on percussion than when the structure of the lung is naturally distended with air. According as the quantity of air is great, so is the sound produced by percussion the more hollow or drum-like, owing to the farther removal of the collapsed or compressed lung from the parietes of the chest, and to the diminished entrance of air into the lung. Hence pneumathorax may instantly be detected by a remarkable contrast of physical signs, namely, by a very hollow or clear sound on percussion of the affected side, with little or no vesicular sound of respiration, while the healthy side gives a duller sound on percussion, but a much more distinct respiratory murmur.

12. Perforation of the pleura, and its consequences, pneumathorax, and the effusion of fluid, give rise to other phenomena which are farther *diagnostic* of these lesions. These are the *sounds* which have been termed the *metallic tinkling sound*, the *amphoric sound*, and the *sound of fluctuation*.

13. (*a*) *Metallic tinkling* has been variously accounted for by several writers, but none of the explanations, and some of them have been sufficiently singular, and others equally laborious, appear satisfactory. This sound is heard most distinctly when the pleura is perforated, when much air is enclosed in the pleural cavity, and when there is also some fluid effused. It seems to proceed from the air passing, during inspiration, through the pleural orifice of the perforation, which, being partially obstruct-

ed by fluid or mucus, occasions a noise similar to that produced by the breaking of a bubble of air contained by an albuminous or other fluid, and the vibrations, being propagated through the enclosed air, give rise to the *clink*, or *metallic sound* or *tinkling* in question. According to this explanation, although perforation of the pleura most commonly causes this sound, it may, nevertheless, be heard in other circumstances in which air is contained in the pleural cavity, provided that, during respiration, the air in struggling through a fluid forms bubbles, which, breaking on the surface of the fluid, causes a vibration which is propagated throughout the included air. From this it will follow, that whatever occasions such a degree of motion of the parietes of the chest, even *percussion* during the physical examination of this cavity, may occasionally develop this sound, which has so long puzzled many stethoscopists, which has mystified others, and which has concerned some but little who have paraded the stethoscope as a most serviceable instrument of charlatanry and humbug.

14. (*b*) The *tinkling sound* may thus present several modifications. Where the perforation is protected or obstructed by its position against the walls of the chest or below the level of the fluid, the tinkling may not be heard unless upon coughing or taking a full inspiration, so as to cause bubbles to be formed in the affused fluid. But the smallness of the perforation, provided that air passes through, will not prevent or obscure the sound, as Dr. WILLIAMS has supposed. "When the orifice is large and free, the air will pass in and out in ordinary breathing, and will produce in its vicinity a sound like that of blowing into the mouth of a glass bottle," or the bung-hole of a small cask, and hence this sound has been called *amphoric*. In these cases the diseased lung is merely collapsed, not compressed by the accumulation of air in the cavity as when the perforation is small, and as it is described above (§ 8-10).

15. The tinkling or metallic sound may be heard only in certain parts of the chest; only where the lung is non-adherent, and where the effused liquid does not reach; only where a cavity is distended by air so as to give the parietes of the cavity a certain degree of tension, and to furnish the condition upon which the sound chiefly depends. In the sitting posture, this sound is heard best about the mamma, and lower part of the axilla and scapula; but in those cases in which the accumulation of air and the distention of the parietes are the greatest, it may be heard in every part of the affected side; while in others, where the collection of air is small, it may be heard only at one spot.

16. When there is a liquid effused into the pleural cavity as well as air contained in it, the diagnosis is generally easy. Percussion shows the level to which the liquid rises, according as it varies with the position of the patient. The motions of the liquid, also, especially upon coughing, will also often give evidence of the presence of air in the cavity. Dr. WILLIAMS has stated that, "on change of posture and on coughing, the liquid will sometimes drop from the parts which have just been immersed; and the sound of this will exhibit the metallic ringing in so distinct a manner, that it resembles

the note which a glass or porcelain vessel yields when struck." (P. 132.) I think that Dr. WILLIAMS is mistaken in this; for, however change of position may produce this sound, whether as I have explained it or otherwise, I am certain that no dropping takes place, or can possibly take place, in the physical circumstances of the parts; but that, in all changes of position which can possibly be made, however extreme or opposite, the fluid will merely run down the parietes of the cavity, without dropping in any part.

17. (c) If the patient be shaken forcibly, or if he give the trunk a jerk, or an abrupt turn or shake, the sound, which was first mentioned by HIPPOCRATES as resembling the *splashing* of water, will be distinctly heard. This sign has been aptly termed *Hippocratic fluctuation*, and is heard when the ear is applied to the side at the time of *succussion*; the tinkling sound being also heard to accompany or to follow it, as the air bubbles break on the surface of the fluid or at the pleural orifice of the perforation. Fluctuation or splashing is best heard when there is much air in the cavity and a moderate or considerable quantity of liquid. Percussion will frequently indicate the proportions, if carefully performed.

18. III. The PROGNOSIS of pneumathorax is very unfavourable, not so much as regards the presence of the air in the pleural cavity as the lesions of which it is the consequence. Pneumathorax most frequently, especially when supervening at an advanced stage of tubercular consumption, rapidly hastens a fatal termination; but in more favourable circumstances, or earlier stages of that malady, life may be prolonged for some indefinite time after its occurrence; rarely, however, for a longer period than a few months. Dr. HOUGHTON has recorded a case of a bricklayer who lived eighteen months after perforation had taken place, and who might have lived longer if he had not imprudently exposed himself in his business, for the signs of a cavity had disappeared, the side had contracted, and his general health had much improved. Dr. STOKES has adduced the case of a gentleman who lived for many months, and who generally heard a splashing noise in his chest when on horseback. CAMBALUSIER and LAENNEC refer to cases which they consider to have recovered, but upon insufficient evidence. Dr. WILLIAMS states, that he has seen "two cases leave the hospital with the impression that they were nearly well, having gained flesh and lost the worst phthisical symptoms after the first severe consequences of the perforation had subsided." (P. 133.) My experience leads me to conclude, that, when the tuberculous disease is limited, when perforation occurs at an early stage of that disease, and when the constitutional powers of the patient are not much impaired—circumstances in which perforation rarely takes place—then life may be prolonged for a considerable period, if a cure even may not be effected. For it is not impossible for a superficial tubercle, or very small cavity, to perforate the pleura, and, by such perforation, or the rupture of the nearly perforated pleura, to allow the passage of air into the pleural cavity, the compression of the lung, and the exudation of lymph upon the surface of the perforated membrane, favouring the diminution or obliteration of the cavity,

and the occlusion, or even the cicatrization of the aperture. In these circumstances, therefore, it is not unreasonable to hope for a considerable prolongation of life, even although complete recovery may not take place. M. LAENNEC has adduced an instance in which the patient lived six years after pneumathorax appeared; and M. CHOMEL has considered perfect recovery not impossible, the parietes of the chest falling inward, as in recovery from certain cases of empyema (*see* PLEURA, § 78).

19. IV. TREATMENT.—This should vary with the several circumstances under which perforation or rupture of the pleura and the passage of air into the pleural cavity take place, with the period which has elapsed since the occurrence, and with the existing state of the patient. When the perforation and passage of air into the cavity have just occurred, the patient often presents many of the indications of having received a vital shock; he is pale, anxious, faint, feeble, and depressed physically and morally. At the same time, he complains of oppressive dyspnoea and pain, and his pulse is rapid and feeble. In this state lowering measures would be dangerous. Gentle restoratives, with opiates, are chiefly indicated, as camphor or ammonia, with morphia; but reaction often occurs, if the accumulation of air and the suffocative dyspnoea (§ 8, *et seq.*) prevent not its supervention. Nevertheless, the irritation and inflammation of the pleura produced by the air are generally attended by some indication of reaction after some hours, although this may be imperfect, or but slightly developed. The pain which is complained of should not be considered as a proof either of the presence or the amount of inflammation, or even of irritation of the pleura, for it is often greatest immediately upon the perforation and passage of air into the pleura, and before inflammation is developed by the occurrence. Besides, it is often occasioned by the stretching of adhesions which had existed, and is thus, as well as in other circumstances, independent of inflammatory action. Still we should be prepared for the supervention of inflammatory irritation of the pleura soon after the air has acted upon this surface, especially if the atmosphere at the time be cold and dry; and this complication of inflammation with the pneumathorax will be more certainly indicated by the states of the pulse, skin, and tongue than by the amount of pain. If the pulse become hard or constricted, the skin dry, and warmer over the affected side, or if the parietes of the side are tender or sore upon pressure or percussion, and if the patient be young, robust, or plethoric, or of the sanguine temperament, then blood-letting, general or local, the latter most frequently, but the former in some instances, and both in others, especially in the circumstances just stated; antimonials, mercurials, and opiates; cooling diaphoretics, aperients, and external derivatives and counter-irritants, as advised for *inflammations of the pleura*, are the means chiefly to be relied on. But these means should be directed with due attention to the peculiarities of individual cases, as insisted upon in the preceding article.

20. Instantly upon the occurrence of this lesion—within even a few minutes of it, as I have seen in one instance—but at any indefinite period afterward, the quantity of air drawn into

the pleural cavity may be so great, and the distention of the parietes of the side so very considerable, as to suggest reasonable fears of almost immediate suffocation, not only from complete compression of the lung of the affected side, but also from a less compression of that of the other side. In these circumstances, exit should be given to the air by puncturing the parietes of the thorax. I am aware that the propriety of resorting to this mode of relief has been questioned; but an instantly impending fatal result has to be averted; and in some instances it may be averted for a considerable time, almost always for a short time, and possibly for months, or even years, by resorting to this operation. I believe that recourse to this operation should not be delayed when pneumothorax has occurred at an early period of phthisis, or when the patient is young, not greatly reduced, or while he has not advanced very nearly to a probable termination of a disease which would certainly end fatally, even if perforation of the pleura had not taken place. The pain and risk of the operation are nothing in comparison with the continued distress experienced during the pneumothorax; and although relief may be only temporary, the operation may be repeated several times without increasing the risk of life, but, on the contrary, greatly diminishing it.\*

21. It is unnecessary to remark farther respecting the treatment of pneumothorax, inasmuch as the means which have been recommended for chronic pleurisy and empyema are generally applicable also for the more complicated malady which has just now been considered, due regard being had to the peculiar features of individual cases. (See art. PLEURA, § 175, *et seq.*)

\* In 1833, a case of pneumothorax occurred in my practice, at an early stage of phthisis; the patient being young and robust, and not having lost flesh or strength. The nature of the mischief was prominently characterized: the heart was pushed remarkably far to the right side; and the rational and physical signs were all marked and extreme; the dyspnea and distress were great. I advised that an opening should be made for the exit of the air; and the friends of the patient desired that Sir A. COOPER should make it. We met a few hours afterward; he admitted his ignorance of the nature of the lesion. I fully explained the cause of the symptoms, and of their extreme urgency; but he refused to perform the operation, stated that he had never performed it with the view of letting out air, and that he would not now do any thing so novel, although he would have been ready to undertake it when he was a much younger man. Having heard Sir ASTLEY's determination, the patient's friends would not allow the operation to be resorted to by any one else; and the patient died, asphyxied, a few hours afterward. The operation, if it had been resorted to in this case, might have prolonged life for a very considerable period.

## POISONS—POISONING—POISONED—SYMPTOMS AND TREATMENT OF.

### CLASSIF.—GENERAL AND SPECIAL PATHOLOGY AND THERAPEUTICS.

POISONS may be DEFINED to be *substances which act injuriously upon the human body*. The number of substances which may be comprised under this definition, even in the present state of our knowledge of the productions of the three kingdoms of nature, is very great; and many of these, owing either to their weak powers, or to the imperfect state of our knowledge of their effects, will receive only a slight notice, or be entirely overlooked. It should, however, be recollected that there are many substances which act injuriously when improperly employed either as articles of food or as medical agents; this improper employment having reference rather to the quantity used, and the conditions of the frame in which it is employed, than to the injurious nature of the substance. The definition, therefore, may be extended as follows: *Substances which exert a deleterious influence on the human frame, when taken internally or applied externally, as regards either their nature or the quantity of them employed; or which tend, in either respect, to destroy life when thus used.*

1. While the word *poison* refers to the substance exerting the deleterious influence, *poisoning* is the commission of the injurious act, and *poisoned* is the state or effect resulting from the substance or agent employed. These words may thus be viewed as referring respectively to the *agent*, the *act*, and *actor*, and the *effects* or pathological states produced by the poisonous agent. It is obvious that the investigation of the *first* and *second* of these, with due precision, belongs to *legal medicine* or *medical jurisprudence*, and that it consequently does not fall within the scope of my work. I have only briefly to consider the *symptoms* and *effects* of *poisons*—the *pathological states* produced by substances, whose injurious effects have been observed and recorded by medical authorities, and the best *means* of *preventing*, *counteracting*, or *removing* these states. Before, however, I venture to discuss the pathological effects of individual poisons, and the treatment of these effects, I shall briefly consider, 1st. *The modes in which poisons are employed or exhibited.* 2d. *The action of poisons.* 3d. *The channels through which poisons act in producing their effects.* 4th. *The general effects of poisons;* and, 5th. *The special operation of poisons.\**

\* The following *Synopsis* will show the extent of consideration which a due discussion of the subject now before me ought to comprise. My limits, as well as the scope of the work, will admit only of a hasty view of the several topics here enumerated:

1. MODES IN WHICH POISONS ARE EMPLOYED OR EXHIBITED.
  - i. To the Respiratory organs—Inhaled or Inspired.
  - ii. Taken into the stomach.
  - iii. Applied externally—(a) The cuticle not having been removed.
  - (b) To a surface the cuticle of which has been removed.
  - (c) Introduced by or into a wound.

2. I. THE MODES IN WHICH POISONING TAKES PLACE, whether the act is felonious, intentional, or accidental—whether it is suicidal or from intentional exposure to the agent—are more diverse than may appear on a hasty view of the matter; and the effects produced and the treatment required are thus equally diversified: 1st. *Several gases, vapours, or fumes of volatile or vaporizable substances have been intentionally exhibited, or accidentally inhaled, so as either to arrest the respiratory actions, or to impede or obstruct, or otherwise influence the changes produced in the blood by respiration, as well as those changes of function, and sometimes even also of organization, which take place either primarily or consecutively in the nervous centres.* Several vapours or fumes, medicinal as well as poisonous, may be inhaled into the lungs with the view of producing certain anticipated effects. Some of these are thus employed more or less beneficially. Others are more obviously injurious, or even fatal; and a few have recently been directed to purposes which are considered beneficial, after the very superficial and empirical view which has hitherto been bestowed upon this mode of employing them. The vapours of several substances possess the power not only of impeding the changes produced in the blood by the air during respiration, but also of altering the physical characters of the blood itself and the

state of the nervous functions. These alterations of the blood and nervous systems are produced not only immediately upon the blood circulating in the capillaries of the air cells, and upon the organic nerves supplying the respiratory organs, but also consecutively, owing to the passage of the vapour to some amount into the circulation, and to the actual admixture of it in the blood, and to its action on this fluid and on the nervous centres. The vapours of alcohol, of all strong spirituous liquors, of most ethereal fluids, of spirits of turpentine, and several volatile oils, produce a more rapid effect when inhaled in more or less concentrated states than when these substances are taken into the stomach; and if the vapour inhaled be much concentrated, or if the inhalation be continued for some time, the changes produced in the blood, and the effects on the nervous system, are such as to endanger or to destroy life. This more immediate and intense effect arises chiefly from the extent of surface upon which the vapour acts, and from the rapid imbibition of fumes or vapours by the respiratory mucous surface. But this subject will be more fully shown in the sequel, when the special operation of certain injurious agents is considered. Most of its pathological and therapeutical relations are discussed in the article ASPHYXIA.

3. 2d. The most frequent way in which poisons are exhibited is *that by the mouth, the injurious substance being taken into the stomach either alone, or simply diluted, or in the drink or food.* It is obvious that the symptoms and the effects of any poison are much modified by the state of dilution or of admixture with alimentary articles when thus exhibited, and by the condition of the stomach at the time, especially as regards the nature and amount of the contents of this viscus. The state of the constitution and of the health, and other circumstances connected with the person poisoned, as well as with the agent employed, also materially influence the effects produced in different cases by any individual poison, although the quantity exhibited is the same. The rejection by vomiting of a portion of the poison, the time that has elapsed from the moment of exhibition, the amount and character of the evacuations it may have produced, and the precise nature and character of the effects observed at the period when the patient has been first seen by the physician, require, both individually and in connexion, to be duly considered by him, the inferences which he must promptly draw from these being made the basis of the most prompt measures of aid. The digestive mucous surface being protected by a mucous secretion, and by the secretions furnished by the collatitious viscera, and frequently containing more or less partially-digested matters, in addition to the vehicle of the poisonous substance, an injurious effect is produced upon it much less readily in many instances, owing to these circumstances, as well as to the nature of the poison employed, than upon some other parts where the poison is more rapidly absorbed and carried into the circulation. Besides, the injurious substance is often in great part thrown off the stomach, or passed through the bowels; and that which remains, by irritating and inflaming the villous surface, is thereby prevented from being absorbed, or so entirely absorbed

- (d) Injected into blood-vessels.
- iv. Injected into the larger bowels.
- v. Introduced or injected into the sexual organs.
- vi. Injected into the urinary organs.
- II. THE ACTION OF POISONS.
  - i. Poisons act locally and primarily.
  - ii. Remotely and consecutively.
  - iii. Both locally and remotely.
  - iv. Chemically.
- III. CHANNELS THROUGH WHICH POISONS ACT.
  - i. Primarily and locally.
    - a. On the nerves of the part.
    - b. On the capillaries and vessels of the part, and the contained fluids.
    - c. On the irritability of the tissues.
    - d. On the general structure of the part.
  - ii. Sympathetically, or by nervous influence; or through the media of the organic and animal systems of nerves.
  - iii. Organically, or by imbibition or endosmose, and absorption; or through the medium of the circulating fluids.
- IV. GENERAL EFFECTS OF POISONS.
  - i. Depressing nervous influence and vascular action; lowering vital power.
  - ii. Inordinately exciting nervous influence, either organic or animal.
  - iii. Inordinately exciting vascular action.
  - iv. Exciting nervous influence and vascular action; exciting vital power.
  - v. Exhausting nervous influence; or exhausting vital energy.
  - vi. Altering nervous influence and vital power.
  - vii. Producing a succession of two or more of these states or effects.
- V. SPECIAL OPERATION OF POISONS.
  - i. Abstracting the animal caloric or depressing the calorific process in a part, or throughout the body.
  - ii. Benumbing, depressing, or suppressing sensibility, or the organic nervous influence.
  - iii. Paralyzing involuntary motion and voluntary movements.
  - iv. Softening, liquefying, or dissolving one or more tissues or textures.
  - v. Irritating particular organs or parts.
  - vi. Astringing and increasing the tone or vital cohesion of certain tissues.
  - vii. Diminishing or increasing the irritability of contractile parts.
  - viii. Augmenting certain secretions and excretions.
  - ix. Stimulating the ganglial, spinal, or sensory nerves.
  - x. Altering the vital actions—the secretions and nutrition of particular organs or textures, according to the substance employed, and the mode of employment.

as it might otherwise be, into the circulating fluids, absorption, imbibition, and endosmosis not so readily taking place in these circumstances as in others. Nevertheless, the injurious impression made by the substance taken into the stomach upon the nervous systems, and especially upon the organic or ganglionic, may continue or may increase, and be extended to several of the collatitious viscera, and even to remote organs, as the brain, spinal cord, heart, lungs, and kidneys—to the former by nervous communication, and to the latter partly by this channel, and partly through that of the blood and vascular system, either mode of operation predominating in different cases, according to the poison which has been taken. I need not, however, dilate farther on this topic, as it will receive numerous illustrations in the sequel.

4. 3d. *When poisons are applied to the external surface of the body*, the effects are contingent upon the state of the cuticle, which forms an efficient protection against injurious substances, excepting such as are most irritating or virulent; and even many of these latter are inoperative, unless they are allowed to remain applied to the surface for a considerable time.

—(a) *The protective power of the cuticle varies in different temperaments and constitutions*, substances which produce little or no effect when applied to the cutaneous surface of one person rapidly affecting others when thus employed. This difference most probably depends upon the varying grades of density, thickness, &c., of the cuticle, and possibly, also, upon the vascularity and sensibility of the subjacent tissues.

5. (b) *Poisonous substances, applied to the skin after the cuticle is removed*, or even to a mucous surface, but more particularly to this surface when its epithelium is detached, produce their effects with great rapidity, the period varying, however, with the situation, the duration of contact, and the nature and state of the substance. The effects depend upon the nature and intensity of the impression made upon the tissue, upon the sensibility and vascularity of the part, upon the rapidity and amount of imbibition and absorption, and upon several other circumstances, which will be more fully set forth hereafter.

6. (c) *When a poison is inserted in a wound*, the effects will be nearly co-ordinate with those which result from its application to a surface deprived of its cuticle or epithelium, some variation, probably, resulting from the nature and situation of the wound, and upon the degree in which the injury may favour the retention, and the situation facilitate the absorption of the poison.

7. (d) *The passage of the poison into a vein, or the injection of it into a vessel*, is productive of the most rapid effects, relatively to the operation of the particular agent employed; for not only is a local effect thereby produced, but the poison, being directly carried into the circulation, operates, according to its nature, both upon the blood and vascular system, and upon the nervous centres, and the vital and excreting organs.

7\*. (e) *When a poisonous substance is employed externally in either of the modes now indicated*, the effects depend principally upon

its nature. Numerous specific or other animal poisons, and several virulent vegetable poisons, are thus inoculated; and diffusive or septic inflammation and destruction of the cellular tissue, erysipelas, the contagious exanthemata and fevers, inflammations of the lymphatics, veins, arteries, and glands, various specific diseases, as rabies, smallpox, &c., and other virulent maladies, in which the organic nervous energy is depressed or annihilated, and the circulating fluids are contaminated, are thereby produced. The inoculation of most of these poisons is accidental, but it may be intentional—felonious or suicidal. Certain of these poisons, when allowed to remain in contact with the surface, may produce their usual effects, although the cuticle or epithelium is entire; but when they are brought in contact with an abraded surface, or introduced into a punctured or incised wound, the effects are rapid, and vary in character with the nature of the poison, and the affection of the constituent tissues of the part injured, some occasioning a septic contamination—a solution and disorganization of the cellular tissue, which rapidly spreads, and poisons the circulating fluids; others affecting the veins, and producing asthenic and spreading inflammation of them, with all its worst consequences; several inflaming the absorbents and absorbent glands; and certain others implicating two or more of these, and often the nerves, arteries, and other structures in addition, the secondary and more remote effects being still more complicated, and the ultimate results being often speedily fatal. Numerous illustrations of what I have now advanced will appear in the sequel, when certain animal poisons come under consideration, and may be adduced from the history of infectious and contagious maladies.

8. 4th. *Poisons may be injected into the large bowels*, either accidentally or intentionally, and produce in this situation their peculiar and even fatal effects. Even certain of them may be thus employed medicinally, and, owing either to the ignorance of the prescriber of their influence in this situation, especially in some diseases and states of vital power and action, or to idiosyncrasy of constitution, their operation may be most dangerous or even fatal. Some injurious substances, when taken into the stomach and mixed with the aliments, are somewhat changed by the action of the secretions, while the primary impression produced by them is thereby impaired or modified, and the absorption of them is delayed or prevented, if, indeed, they be not instantly thrown off by vomiting; but there are many which, when thrown up into the large bowels, act more rapidly and more virulently than if they had been taken into the stomach, owing to rapid absorption often taking place in the large bowels, and to the circumstance of their being less likely to be changed in this situation.

9. 5th. *Poisons have been introduced into the sexual organs*, especially of the female, where they have produced their local as well as constitutional effects, the former of these effects being severe according to the nature and quantity of the substance thus employed, and the latter depending upon the same circumstances. This mode of poisoning, as well as the next,

10. 6th. *The injection of poisons into the uri-*

nary passages, is of rare occurrence; it has, however, been employed both feloniously and accidentally; while the treatment of several maladies of the sexual and urinary organs, by means of injections of various stimulating, astringent, tonic, or acrid substances, has caused, either directly or indirectly, most injurious, or even fatal results, especially when these have been resorted to in cases to which they were inappropriate.

11. II. OF THE ACTION OF POISONS.—*Poisons*, according to the definition of the word given above, may act, 1st. *Locally and primarily*; 2d. *Remotely and consecutively*; and, 3d. *Both locally and remotely*. Thus the substance applied either to the external surface, or inhaled into the lungs, or taken into the stomach, may only corrode or inflame the part with which it comes in contact, this effect being so intense as to endanger or even to destroy life. It may produce but little or no lesion or visible change in the part to which it is applied, and yet, through the medium either of the nervous systems or of the circulating fluids and vascular system, it may destroy the individual. And lastly, it may, after having occasioned more or less remarkable local changes, affect the nervous systems, or the vascular system and fluids, or both the nervous systems and the vascular system, with the fluids, secretions, and excretions, thereby destroying life, and sometimes altering even the structure of several of the organs of the body before life is extinguished. Sufficient illustration of these modes of action will appear in the sequel; but I must consider them individually and more particularly, and with reference to the tissues which poisons seem especially to affect, and the channels and media through which they act.

12. I. OF THE LOCAL AND PRIMARY ACTION OF POISONS.—Whether or no the injurious action of a substance be limited to the part to which it is applied, or be extended much farther and to distant parts of the frame, it is of moment that we should have some acquaintance, the more intimate and accurate the better, with the nature of the effect produced locally, and with the changes in the constituent tissues of the part.—(a) Certain substances, as aconitine, prussic acid, &c., even when applied to an external part, protected by its cuticle, will occasion numbness or want of sensibility, without any other visible change, the local effect thus produced in the *nerves* not proceeding farther, unless the application be protracted or repeated, or the activity of the poison be great, or the cuticle be removed. This effect upon the sensibility evinces not merely a special operation of the substance, but also a disposition or power possessed by it to affect more generally and sympathetically the whole nervous systems, although certain parts of this system may betray the effect in a more remarkable degree.

13. (b) Other substances produce a more severe local effect, and yet this effect will continue altogether, or more or less, limited to the part, the injurious operation being caused rather by the intensity and extent of the irritation locally excited than by any other more extended impression or change produced by it. Substances occasioning a local injury or irritation, as mechanical irritants, fragments of broken glass, &c., excite the organic and animal sen-

sibility in the part with which they are brought into contact; and soon afterward the vessels, the capillaries especially, and contractile parts are implicated, and even farther local changes of structure ensue, owing to the effusion of lymph, serum, &c., and to the alterations thereby produced.

14. (c) Certain substances, while they benumb the sensibility of the part to which they are applied, also impair the irritability of the fibrous or contractile tissues; and others, while they excite the sensibility, also increase for a time both the susceptibility and the power of contractile or irritable parts, ultimately exhausting these properties, according to the nature and quantity of the substance employed, and thereby showing the intimate connexion existing between sensibility and irritability, and demonstrating that substances which either benumb or excite, or exhaust the one, similarly affect the other. The more active of these agents may thus destroy life by their local effects, especially when they act upon vital organs or parts. Even mechanical agents or irritants, by their intense action locally, and the nature or functions of the organ, surface, or tissue with which they come in contact, may destroy life by their local effects entirely or chiefly. The changes produced by numerous substances are of such a kind as admit of their usual procession being observed. First, the nerves of the part and the sensibility are either benumbed or excited, or irritated, or exhausted, and the contractile property of fibrous tissues similarly affected. Then the capillaries and the contained fluids are implicated, and all the phenomena, either of congestion or of inflammation, with the usual results, are developed, according to the nature of the agent employed.

15. (d) Other substances act so rapidly, and produce so general an effect upon the constituent tissues of the part, involving them all in the effect produced, or inducing disorganization with so great rapidity as to render it difficult, if not impossible, to determine the particular element or tissue primarily or principally affected, or to trace the procession of changes. Intense heat and cold, numerous chemical agents, and some septic poisons derived from the animal and vegetable kingdoms, produce this more intense and disorganizing effect upon the part to which they are applied. Some congeal, constrict, desiccate, corrugate, carbonize, or otherwise destroy the structure; and others dissolve, liquefy, or annihilate the vital and physical cohesion of the several textures, which fall into a state of dissolution or pulpy destruction with varying degrees of rapidity.

16. II. OF THE REMOTE OR CONSECUTIVE ACTION OF POISONS.—The primary impression or action of poisons is seldom such as to destroy life of itself, or without producing remote or consecutive effects. If, owing either to the intensity of the local action, or to the extensive disorganization produced in the part, death should quickly follow the application of an injurious or poisonous substance, the effect may be imputed chiefly to the shock received by the vital power, unless the agent acts directly upon a vital organ, whose circulation and functions it is capable of immediately arresting. A corrosive substance, as nitric or sulphuric acid,

&c., taken into the stomach, owing either to its nature or the quantity employed, or to both, causes death in a very short time; but this result is not owing merely to the local action, but to the shock produced by a severe injury inflicted upon an organ supplied by nerves from the organic or ganglionic nervous system, and intimately associated in function and organic nervous energy with the organs most necessary to the continuance of life. The local injury is inflicted; the whole body instantly experiences or feels it; the shock, or injurious impression, is rapidly transmitted throughout the whole organic nervous system; and if it be intense, it annihilates not only the vital influence of the organ on which it primarily acts, but also, and through the medium of the organic nervous system, the action of the heart, of the diaphragm, of the lungs, of the brain, &c. Thus the more immediate of the remote effects are produced, sometimes with a rapidity which might lead to the inference that the local impression and the consecutive result are but one operation. More frequently, however, this result takes place with much less rapidity, the primary injurious impression inducing a succession of pathological phenomena, which often admit of due recognition, as they are manifested in either the nervous or the vascular system, or the blood, or the secretions, or the excretions, or in several or even in all these, as will appear in the sequel.

17. It is obvious that, while some injurious agents, from their nature or the quantity, may act either locally or remotely, primarily or consecutively, or in either of these chiefly, there are others which act *in both modes*, either one predominating over the other, according to the agent or agents employed. The mineral acids, in large quantity, or in a concentrated state, act locally, destroy the textures, occasion a general shock of the frame, and even terminate life. In small quantity, or less concentrated, the local action is much less intense, and remote effects are developed, and are such as admit of being traced. Various vegetable or narcotic poisons produce but slight or no apparent local change, yet affect organs remote from the seat of application in a very remarkable manner; and many substances change not only the tissues, on which they primarily act, but also the states of distant parts; these substances even deriving their chief appellations, as acro-narcotics, &c., from their compound properties.

18. III. THE MEDIA OR CHANNELS BY WHICH POISONS ACT.—It is of great importance to trace the channels through which substances act injuriously on the frame; for the knowledge of these enables us on many occasions to prevent or to arrest the effects produced by these substances. But in order that the media or channels of remote or consecutive effects should be recognised, it is necessary, in the first place, to ascertain the local and primary operation of the substance, the more remote effects of which we are desirous of tracing in the successive changes produced by it. It becomes, therefore, desirable to consider, 1st. *The nature of the local and primary impression produced by a poison.* 2d. *The extent and amount of the sympathetic effect, or of the operation by nervous communication or influence as far as this may be*

*known; and, 3d. The organic operation of a poison, or the circumstance of the imbibition and absorption of the substance injurious employed, and the probable extent or amount of the mischief produced which may be imputed to this mode of operation.* As poisons thus act *locally, sympathetically, and organically*, or in the ways now specified, and as it is obvious that the action of a particular poison is not limited to any one of these modes, although it may operate in either way more prominently than in the others, it may not be superfluous to consider the matter more in detail.

19. i. *The nature of the local and primary impression produced by a poison* is not always readily ascertained; for, owing either to the quantity or the intensity of action of the substance employed, the several constituent systems and tissues of a part may be so instantly and generally impressed and altered by that substance as not to furnish distinct evidence of the tissue primarily affected, as I have above contended; but in other circumstances the local changes, as well as the consecutive effects, often admit of analysis, although sometimes imperfect, the results necessarily varying with the circumstances of particular cases.

20. A. *The nerves* of the part, whether the organic, the sensory, or the motory, are evidently primarily affected according to the texture to which the poison is applied, or are the first to manifest the effect, unless the substance be such as rapidly to change the organization of the structure; and according as either of these orders of nerves is implicated or impressed, so will the secretions, the sensibility, or the movements of the part be affected.

21. B. *The irritability* of contractile tissues is also altered by poisons, more especially by those which change the state or functions of the organic nervous system. If what I have contended for in the article IRRITABILITY, namely, the dependence of this very prominent vital property upon the organic nervous influence, be admitted, it necessarily follows that this property will be co-ordinately affected by whatever changes the state of this influence; and a close investigation of the operation of many poisons proves that those substances, as certain animal poisons, which inordinately depress or altogether annihilate this influence, affect the irritability of the contractile tissues in a similar manner and in a co-ordinate degree.

22. C. *The capillaries and vessels* of the part must also be changed, as regards their vital properties, whenever the organic nervous influence and irritability are affected; and the change of these vessels must be necessarily similar, as to kind and degree, with that primarily produced in the organic nerves and contractile tissues. There is every reason, also, to believe that the change is not limited to the capillaries and smaller vessels, but extends more or less manifestly to the contents of these vessels, more especially to the red globules and to the fibrin of the blood which they contain; the condition of the former constituent of the blood in these vessels, and the quantity or state of the latter, being always very materially altered by the morbid impression made upon the organic nervous influence and irritability of the part, and upon the vital properties of the capillaries, the physical and chem-

ical characters of the blood in these vessels being thereby thus rapidly changed.

23. *D.* The alterations thus produced in the organic nervous influence, in the irritability, in the state of the capillaries, and in the contents of these capillaries—in the blood—of a part to which a poison has been applied, must necessarily soon be followed by farther changes in the whole of the tissues constituting the part—in its *whole structure*—and these changes will be rapid, extensive, and diversified in character, according to the nature of the poison, and as it acts prominently upon either the nerves, or the capillaries, or the fluids, or the other constituents of the part, or in any of the particular modes which will come under consideration in the sequel.

24. *ii.* *The sympathetic operation of poisons*, or the action of a poison on parts remote from that to which it is applied by means of the nervous system, or by any of the orders of this system—the organic, the sensory, and the motory—evidently obtains to a very considerable extent, especially as respects the action of some poisonous substances; but, as this medium of operation is not the only one, and as it is frequently associated with that about to be considered, namely, the blood and vascular system, either channel being more or less operative in producing the remote effect, according to the nature of the substance and state of the system, it is often difficult to determine the precise extent to which either contributes to the ultimate result. It will, however, be shown in the sequel, that certain substances, when taken into the stomach, or injected into the bowels, or otherwise brought into contact with parts supplied chiefly with the organic or ganglionic nerves, have not merely the sensibility of these nerves excited, but also the involuntary movements of parts distant from that to which the substance was applied remarkably affected, owing to the local irritation being transmitted through the medium of this order of nerves, and the connexion of these nerves with nerves of sensation, and with the roots of the spinal nerves; and, farther, owing to this connexion, the effects are often extended to the spinal cord and to the brain, and thence reflected upon voluntary muscles and the extremities of the body, the resulting phenomena varying with the nature of the injurious agent and the temperament and constitution of the person poisoned by it. It is unnecessary to illustrate this topic at this place, as it is fully discussed in the articles *IRRITATION* and *IRRITABILITY*, and especially in that on *SYMPATHY* or associated morbid states.

25. *iii.* *The organic operation of poisons*, or the imbibition and absorption of them, or the action of them through the media of the circulating fluids, as the lymph, the chyle, and the blood, is one of the most important ways in which the effects of these substances are produced. Still, this way is not always the same, the route varying with the organ or part to which the poison is applied, and with the nature and action of the particular poison employed. The imbibition or endosmosis of some substances through membranous tissues is often much more rapid than that of others; but much depends upon the physical state of the poison, and concentration of the solution of it employed, and other circumstances. The passage of

some substances into the blood, when either applied to a mucous surface, or to a surface denuded of its cuticle, or epithelium, or introduced into a wound, is often much more rapid than might be supposed, if the fact had not been demonstrated by experiments. Nevertheless, the rapidity of the introduction of certain poisons into the circulation has been, according to a few observations I have made, overrated by some writers, who have considered that the passage of a poison into the blood may take place in a very few seconds. It will certainly occur in much less than a minute in some cases; but I doubt the extreme rapidity contended for by some physiologists. Great rapidity of absorption is observed chiefly as respects certain saline or virulent vegetable and animal poisons, which are readily imbibed by the capillaries and carried into the blood. Substances which are absorbed by lacteal or lymphatic absorbents act much more slowly, and several of them require a considerable period before they reach the blood, especially if the vessels which have absorbed them pass through glands; and when this is the case, the glands are often affected, and in some instances, when the poison is not very virulent or rapid in its operation, the glands either altogether arrest or delay, for a longer or shorter time, the progress of the mischief.

[It is now generally conceded that poisons are not instantaneous in their action, but that sufficient time always elapses between the application of a poison and the first symptom of its action to admit of its contact with the tissue which it affects. Thus, hydrocyanic acid requires, according to Professor BLAKE, of St. Louis, eleven seconds before it will take effect, when applied in large quantity to the tongue of a dog; and death does not occur under thirty seconds. He found fifteen seconds elapsed after ten drops of *conia* had been injected into the femoral vein of a dog, before symptoms of the action of the poison appeared; and death did not occur until thirty seconds after the injection. Dr. B. has also showed that the time required for a substance to be absorbed by the capillaries and diffused through the body, may not exceed nine seconds. The same experimenter has proved that the celerity of action of any poison is in a direct ratio with the rapidity of the circulation: a fact of great importance as connected with the *modus operandi* of medicinal as well as poisonous agents.]

26. The poison having been carried into the circulation either by the lacteal absorbents, or by the lymphatics, or by the capillaries and veins, according to the seat or part to which it is applied, and the action which it exerts on the constituent tissues, produces ulterior effects, which are about to be briefly considered, owing to its action, 1st, on the blood itself, in which it mixes, and which it contaminates; 2d, on the blood-vessels and heart; 3d, on the nervous ganglia and plexuses; 4th, on the spinal cord and the sensory and motory nerves; and, 5th, on the brain and organs of sense.

27. *iv.* Those poisons which act more or less *chemically* are most readily imbibed, are absorbed most directly and rapidly, and change not only the physical characters, but also the chemical constitution of the blood, as far as we are acquainted with that constitution. They

change the colour, and there is reason to suppose that they affect also the organization of the red globules; they alter or diminish the fibrin, and variously affect the saline and albuminous constituents of the blood. But there are few of those substances which act thus chemically upon the blood, especially alkalis, acids, and numerous neutral salts, that do not also affect the vital condition of this fluid, and change this condition and its chemical constitution both in relation to each other, and in connexion with the vessels and heart, and with the nervous centres, more particularly the nervous system actuating the circulating apparatus.

28. IV. GENERAL EFFECTS OF POISONS.—i. *Some substances or agents depress nervous influence and vascular action*, and thereby lower vital power; the depression being either relative or absolute, and varied in its effects, according to the agent and the quantity, intensity, or duration of its operation. The application, for instance, of cold, or, more correctly, the abstraction of vital caloric, when moderate or of short duration, or acting upon a surface or part only of the body, depresses vital action in that part during its continuance; but reaction takes place when the depression is limited as to seat and time, owing to the determination of the circulation to more internal or to vital parts, or when muscular action accelerates the flow of blood in the vessels. But when cold, owing to its intensity or continuance relatively to the state of the system while exposed to it, renders torpid the organic nervous influence, and retards or interrupts capillary and venous circulation through a considerable extent of the frame, reaction may not take place, or may occur so imperfectly or irregularly as not to relieve internal congested organs; and if it occur, it may be attended with, or develop inflammation in some predisposed organ.

29. There is, perhaps, no other agent which tends so completely to depress both the nervous and vascular functions, so as even to overwhelm them altogether, as cold, when it acts either intensely or for a long period relatively to the constitution and circumstances of those subjected to its influence, or when it exceeds in grade that which has just been stated to admit only of imperfect reaction. Like other agents, therefore, cold is either a tonic, a sedative, or destructive of life, according to its grade and the manner of its operation on the living economy; but there is scarcely another physical agent whose sedative effects are so equally manifested upon all the general systems and functions of the frame, and without directly producing some other operation, unless the respiration of air, loaded with carbonic acid, or with sulphureted hydrogen, or prussic acid used in any form, be exceptions. Aconite and colchicum are sedatives to the sensory and organic nerves especially, but they also irritate the surfaces to which they are applied; and digitalis and tobacco act chiefly on the heart and vascular system, without materially depressing the nervous functions of animal life, or the functions of the brain and spinal cord. When, however, these, or other substances, which produce a general sedative or depressing effect, as respects nervous influence and vascular action, are exhibited in large or injurious

quantities, their subordinate operations are then so masked as to escape notice, or are so inconsiderable as not to deserve attention. Certain poisons, which produce a narcotic effect upon the nervous system, when given in moderate doses, exert a sedative influence upon the vital actions generally, when taken in still larger or poisonous quantities, as shown by opium, belladonna, conium, hyoscyamus, &c., when so exhibited.

30. The sedative effect, when it becomes injurious, is generally not limited either to the part to which the agent is applied, or to a particular system or organ. Besides depressing nervous power in the surface or viscus to which a sedative poison is applied, and causing capillary and venous congestion, the morbid impression is propagated along the nerves to more distant parts, especially to the nervous centres, while the poison itself is partially absorbed, and, mixing with the blood, it acts directly upon the nervous masses, and more or less, also, on various organs, according to its specific influence. This being the general effect—the result being depressing, and ultimately destructive of organic nervous power and vascular action, with varying degrees of rapidity, according to the nature of the poison and the quantity employed—it may be imputed, according, also, to the nature and quantity of the agent, to either of these channels or media principally, or to all of them, although in different grades, the fatal or injurious operation arising through these sources singly, or conjointly, but in varying proportions.

31. ii. *Some poisons inordinately excite nervous influence and vascular action*, or stimulate vital power for a time. Heat and oxygen are the most influential agents in producing this effect, and they perpetuate it perhaps longer than any other without exhausting vital action, especially upon withdrawing them. Alcohol, the ethers, ammonia, and numerous other stimulants, may become poisons when exhibited in large quantities, or when long employed, owing partly to their effects locally, but especially to their influence, through the media of the nervous and vascular systems, and of the blood, upon the nervous masses or centres, and upon the liver and excreting organs. It is seldom, however, that stimulants destroy life before they have induced either exhaustion co-ordinate with the stimulating action, or effusion to an amount sufficient to interrupt the functions of a vital organ, or alterations of the circulating fluids incompatible with the continuance of the nervous functions or of the heart's action, or even inflammatory or structural changes of some important viscus, or some two or more of these changes.

32. iii. *Exhaustion of organic nervous power, and of sensory and motory influence*, or of vital energy generally, is one of the most manifest general effects of substances given in quantities sufficient to destroy life in a short time. This exhaustion is especially remarkable when it is caused by substances which injuriously impress the nervous systems, or which act so rapidly as to render it difficult to determine whether the impression of the agent be transmitted by means of the nerves to the heart and brain, or whether the substance is itself absorbed into the circulation, where it directly

acts upon these organs, or whether it acts in both ways. Poisons which may be said to kill by exhausting the vital actions must necessarily be considered as having first produced an excessive stimulating effect, which has so rapidly passed into exhaustion as to leave the primary operation unobserved or even unobservable, for exhaustion implies antecedent stimulation. Nevertheless, if the operation of many of the substances which are generally said to destroy life by exhausting vital power, when given in large quantities, be considered with reference to their effects upon the living economy in small doses, it will be found either that the quantity which is stimulating is very small, or that the stimulating operation of the substance, even in such quantity, is very equivocal; and, if it may be admitted to exist, it rapidly lapses into a distressing or peculiar form of exhaustion, as may be allowed in respect of tobacco and various narcotics. From this it will appear that the poisonous effect of the same substance may be imputed by one person to the powerful sedative effect it had produced in the quantity or dose in which it had been given, and by another to the extreme exhaustion consequent upon a great and rapidly evanescent stimulation, &c., according to the views each may entertain of the physiological action of the substance in question.

33. iv. *The general effects of poisons cannot be viewed as merely dynamic: they also alter or change the states of nervous influence and of vascular action.* Those substances which prove rapidly poisonous, owing to their nature or the quantity taken, evince the dynamic operation more remarkably. This may, however, be owing to the circumstance that the dynamic action is much more recognisable than any change in character or kind of action, during the short period intervening between the impression of the agent and a fatal result. It is chiefly such poisons as act slowly, or some of those which are more virulent, but which, when taken in small quantities, are not rapidly fatal, that produce more or less manifest alterative effects. Still, these effects are not solitary; they are generally associated with one or two of the general effects already noticed, and also with certain others, which are more specific, or which appertain to the poison in question, and in some respects characterize its operation when employed either medicinally or otherwise. The alterative effects of poisons being recognised with difficulty, in connexion with other more general and remarkable results, unless the operation is slow, and as these effects are more peculiar or specific, and, at the same time, more complicated, I shall proceed to consider them more in detail, and endeavour to analyze them, or show their more special influences, although I cannot do so at this place in so full and satisfactory a manner as I am desirous of doing.

34. V. *THE SPECIAL OPERATION OF POISONS.*—It is obvious to the experienced observer of the operation of the more active agents of nature upon the living economy, that very few act in one unvarying manner, or that any one of them produces a single effect, or acts solely upon a single function or part, without also affecting others more or less. All that such an observer of the more special actions, either of

medicines or of poisons—and most of the former possess the latter property—can expect, is this, that, although any one of these substances produces certain general results, and extends its influence more or less to different functions and even to remote organs, some particular surface, function, or viscus; some one of the chief factors of life, or of the constant actions and results which these factors produce; some of the manifestations of life in particular tissues, systems, organs, or parts, will be more prominently affected than others, or be chiefly, but not solely, changed by the action of that substance. In the analytical survey I am about briefly to take, it must, therefore, be considered, that the special action of any single poison is not confined to the production of one only of the several effects which I shall have to notice under the separate heads which the analysis furnishes; but that it extends to more than one system or viscus, although some one manifests it much more than another, and alters certain vital properties and functions, or a particular property or function, more than others. When the symptoms and changes produced by individual poisons, and the modes of obviating and removing these changes, come under consideration, then the associated and even complicated nature of these changes will be made more evident.

35. i. *Some injurious agents abstract the caloric, or depress the vital calorific process not only in the part to which they are applied, but also throughout the body.* This effect may be produced by the application of cooling substances, or by whatever lowers the organic nervous influence and vascular action, or by both modes of action produced either simultaneously or in rapid succession. A large quantity of cold water or of ice taken into the empty stomach, especially when the system is exhausted by fatigue, or when the body is perspiring freely, may not only abstract the animal heat from parts requiring a certain elevation of temperature for the performance of their functions, but also depress the organic nervous influence actuating these parts, so as to produce capillary and venous congestion, or an arrest of the circulation, and other consecutive effects, until the action of the heart ultimately ceases. Although cold fluids may destroy life very rapidly when taken largely in these circumstances, in the manner now stated, and owing to the influence of cold upon vital actions, as noticed above (§ 28, 29), yet there are hardly any substances which are poisonous owing chiefly to this mode of action, although there are several which, when employed in large or frequent doses, produce a refrigerating and depressing effect along with other changes of a more prominently injurious nature, more especially the hydrochlorate of ammonia, the nitrate of potash, and various other salts and dilute acids, which not only depress the calorific process, but also chemically and physically affect the blood and vascular system, and through this medium the nervous system also.

36. ii. *Certain poisons act more especially in destroying the sensibility, or the functions of the sensory and of the organic nerves, in benumbing, depressing, or suppressing sensibility, and the organic nervous influence.* Of these the most remarkable are monk's-hood and its active prin-

ciple aconite, cold; ether and alcohol, when absorbed or injected into the blood, or when their vapour is inspired; belladonna, conium, morphia, and most of those which have been denominated narcotics, sedatives, and stupeficients. But these produce also a paralyzing effect, remarkably depress the organic nervous influence, diminish irritability, impede secretion and excretion, or even irritate the mucous surface to which they may be applied, as colchicum, tobacco, hyoscyamus, opium, &c. [*Chloroform* is another very active poison, which may be ranked under this head, as it exerts a directly depressing influence over the heart and cerebro-spinal system of nerves; and if breathed for a few minutes, would inevitably destroy life.]

37. iii. *Other poisons more prominently paralyze the organs of voluntary motion, while they impair the irritability of involuntary parts, diminish sensibility, and depress the organic nervous influence,* especially hemlock and its alkali, conia, hydrocyanic acid, and the cyanides, carbonic acid, sulphureted hydrogen, &c.; stramonium, cannabis indica, tobacco, digitalis, the preparations of lead, &c.

38. The substances which act energetically upon the nervous system, in impairing either the sensibility or the irritability and the voluntary movements of muscular parts supplied by nerves respectively belonging to these systems, have not their actions limited to one of these functions only, although either may be more prominently affected according to the poison employed. Their effects may, moreover, be extended even to secreting and excreting organs, such poison acting more or less on particular functions than on the others. When either of these substances is taken into the stomach in quantities which are injurious, not only are the nerves of the part affected, but absorption of the poison takes place to a certain extent, and the injurious impression made upon the nerves by it is transmitted along the organic and sensory nerves to the ganglia, brain, and spinal cord, which are farther affected according as the substance is present in the circulation. Some of these poisons seem to affect one order of the nervous system more than another; certain of them impress more especially the organic or ganglial nervous system, deranging the several functions depending chiefly upon it; others affect the brain, consciousness, and sensibility, and impair more or less the voluntary movements and other allied functions; and these several results are, moreover, varied not only with the quantity of the poison taken, but with the circumstances connected with its exhibition and the constitution and temperament of the person who is its victim.

39. iv. *Certain poisons produce a septic action, weakening and dissolving the vital cohesion of tissues, or softening and even liquefying the structures.* These substances not merely depress the organic nervous energy of the parts with which they come in contact, but they also produce a physical or chemical change in the tissues, contaminating the fluids, and favouring the imbibition and absorption, not only of the poison itself, but of the contaminated fluids of the poisoned part. Animal matters act chiefly in this way, more particularly the poisons of serpents, of fish, decomposing or putrid animal

substances, the animal poison generated in sanities and preserved or dried meats, the secretions and fluids in disease, or after death; especially after malignant and infectious maladies, and still more especially if any of these be applied to a punctured wound, or to an abraded surface. In most instances the local action of these poisons is evinced by the part being pained, swollen, livid, or otherwise discoloured, soft or boggy, sometimes numbed, and changed in temperature, often rapidly passing from a burning heat to coldness, or being cold from the commencement. These changes proceed from the extremities to the trunk, from the periphery to the centre, and extend more or less rapidly, with remarkable sinking of vital power, a very quick or irritable pulse, and manifest indications of contamination of the fluids and soft solids, more especially when the poison has been applied to an external surface, or to a wound. When it has been taken into the stomach, distressing nausea, vomiting, anxiety, and feeling of sinking, evidently owing to depression of the organic nervous energy, are then generally observed, with other symptoms varying with the particular poison which has been taken, as cutaneous blotches or eruptions, coldness of the surface, suppression of urine, rapid, weak pulse, watery stools, &c., &c.

40. The animal poisons which act in the way now described affect chiefly the *vital conditions* of the parts to which they are applied; depress organic nervous influence, and loosen the vital cohesion of the tissues, while they contaminate the fluids; but there are other substances, which soften or liquefy the tissues, in consequence rather of a *chemical* than a *vital* operation, although the vital conditions are also to a certain extent affected. These are the *alkalies*, the sub-salts, or those saline substances in which the alkali is the predominant element, the bichlorate of soda, the iodide of potassium, the alkaline sulphurets, the preparations of antimony, of mercury, &c., when used in large quantity or long employed. These substances act locally, more or less energetically, as now stated, especially the pure alkalies; but they are also rapidly absorbed, and they then alter the vital conditions of the nervous and vascular systems, and the chemical constitution of the blood, especially as regards the red globules and fibrin, the proportions of which they even diminish, especially when they have been employed for a considerable time. When thus used, they also liquefy, and favour the absorption of morbid growths or tumours, while they relax generally the soft solids.

41. v. *That various poisons excite the ganglial, spinal, and sensory nerves, or either of these orders of the nervous system, more than the others,* will be admitted; but this effect is generally varied and associated, according to the nature of the particular substance employed, with other changes manifested by secreting surfaces and organs. The stimulating operation is evidently exerted primarily upon the nervous organization of the part to which the substance is applied; and for a time it tends to concentrate the nervous power, and even vascular determination and action, towards the surface or viscus thus acted upon. Subsequently, however, the effects become more or less diffused; but the rapidity of the diffusion of the stimulating influence over

the frame depends upon the nature and quantity of the substance employed, the state of the organs upon which it has acted, and the temperament, constitution, and habits of the subject acted on. The principal question is, whether or no the general or remote effects are produced by nervous influence, or by the rapid passage of the substance into the circulating fluids, and the consequent operation of it upon the several organs and structures of the frame, or by both these modes, either of them predominating according to the circumstances just stated.

42. *A.* As to the action of stimulants on the nervous system, on either the ganglial, the sensory, or motory, or upon any two or all of these divisions of the system, there can be no doubt as respects that part of it supplying the organ to which the poison is applied; the question being as to the extension of the stimulating operation to distant parts by means of this system. Formerly, the remote effect was imputed altogether to this system, the other mode of action just referred to being overlooked or discarded. From 1819 until 1826, I made many experiments with stimulating substances and tonics, vegetable and mineral, some of which were published in the journals of the day (especially in the *London Medical and Physical Journal*, and *London Medical Repository*), with the view of determining the *modus operandi* of many active agents upon the frame; and I demonstrated beyond dispute that this is not the only mode of action, as regarded the great majority of them, which, although acting more or less in this way, operate also, and even mainly, through the medium of the circulating fluids.

43. That the stimulating impression made upon the organic or sensory nerves of the viscus to which the substance is applied is transmitted, more or less remarkably, by means of these nerves to remote parts, which it thus affects, appears extremely probable; for there are several analogies, considerations, and even proofs, both physical and pathological, of this being the fact; and, moreover, these remote effects are often reflected upon other distant parts. Thus the stimulus existing in, or acting upon, an internal viscus, may be transmitted by the organic nerves to the adjoining ganglion, or to the great semilunar ganglion, or to the spinal cord, or to the brain, becoming an object of either obscure or distinct sensation or consciousness, and there the effect may cease, or be reflected thence upon other parts, affecting the actions of involuntary organs, through the media of ganglial nerves, or exciting the movements or sensibility of voluntary parts through the medium of the spinal cord. The remote effect may be produced more or less by either order of nerves or nervous masses, ganglial, cerebro-spinal, or sensory and motory, according to the nature and quantity of the substance employed, and the mode of employing it. Much of the misconception and confusion which have existed as to the operation of agents on and through the medium of the nervous organization have arisen chiefly from the following circumstances: 1st. Experimenters have considered the organic nerves as forming a part of those proceeding from the cerebro-spinal axis; 2d. They have viewed the distinct orders or divisions of the nervous system as identical, and as performing the same functions; and, 3d. They have over-

looked the fact that it is impossible to separate the vascular system from the nervous, so as to isolate each, and that it is equally impossible to cut off the nervous communications existing in distant parts while the arterial communications are allowed to continue, inasmuch as all arteries are surrounded by a reticulum of ganglial nerves. It is owing mainly to these circumstances, and their consequences, that so many ill-planned and ill-performed experiments on living animals have been made; experiments which could furnish no correct inferences, which, moreover, were undertaken to decide points not admitting of being thus decided, and which could not prove the basis of even a loose hypothesis, far less of sound doctrine. Considering, therefore, as will appear more fully in the sequel, that poisonous as well as medicinal agents produce an impression upon the nerves of the part to which they are applied, that is not limited to such part, but which often affects sympathetically distant parts, although in various degrees and modes, according to the nature and state of the substance employed, I proceed to remark upon the operation of stimulants through the medium of the circulation.

44. *B.* That numerous stimulating substances—vegetable, saline or mineral, and animal—are more or less rapidly imbibed by the tissues, and absorbed into, and are afterward eliminated from, the circulation, are among the best established facts in physiological science. The effects which these substances produce, when taken either medicinally or in hurtful doses, are chiefly owing to this mode of action, although the impression primarily made by them on the several divisions of the nervous system is also more or less influential in producing these effects; but the exact extent of that influence can hardly be determined. That the majority of stimulating substances are actually absorbed into the circulation, to an extent varying with the substance employed, and the state and mode of its employment, has been fully established, inasmuch as they have been detected in the blood itself, and in the several secretions and excretions. The special operation of many stimulants thus depend not only upon their primary impressions upon the nervous system, but also upon their presence in the blood, and their action on the nervous masses and centres, and more specifically upon the functions of certain organs and surfaces, particularly upon those organs by which they are eliminated from the blood. The alcoholic, the ethereal, the balsamic, the camphoraceous, and several other classes of stimulants, both vegetable and mineral, act in the way now stated.\*

\* During 1819, 1820, and 1821, I made a number of experiments upon the operation of several active substances; and the results of those which I made with the terebinthines were published in the *London Medical and Physical Journal* for July, 1821. At that time it was generally believed that medicinal as well as poisonous substances acted upon the nervous system directly and entirely, the results depending altogether upon this system, without reference to the blood and vascular system, and without distinction between the organic, the sensitive, and the motory divisions of the nervous system. I believe myself to have been, if not the first, at least among the first, to determine by experiments the action of these substances through the medium of the blood, and to show that many of these substances act differently upon the different orders of the nervous system; upon the organic nerves either chiefly, distinctly, or differently from their action on the cerebro-spinal. (See *Lond. Med. and Phys. Journ.*, July, 1821, p. 112, *et seq.*, and August, 1821, p. 165, *et seq.*)

45. vi. That many poisonous substances are capable of *astringing the tissues and of increasing the tone or vital cohesion of certain structures, when employed in small quantities, cannot be doubted*; but this effect more rarely follows their employment as poisons, unless in the case of mineral poisons; and then the operation of these, especially when used in large or injurious quantities, is more chemical than vital; several of them, as the mineral acids and salts, combining to a certain extent with the tissues and the liquid elements of the tissues, altering the constitution of the capillaries and of the capillary contents, and thereby affecting the state of vital function and action. Many of the substances which act as stimulants, by the greater permanency of their effects, and by their action, in the manner now stated, upon the tissues, have an astringing operation. Substances acting thus on the economy have not their effects always limited to the parts to which they are applied; for I have ascertained that they are absorbed, especially when much diluted, or when dissolved, into the circulation, and are afterward carried out of it chiefly by the kidneys and skin. The metallic salts and the mineral acids severally act in this way more or less rapidly, energetically, and manifestly; and produce their effects on parts of the frame the most remote from those to which they were applied. The metallic sulphates and nitrates, the superacetate of lead, the balsams and resins, the phosphoric, the mineral, and many of the vegetable acids, although acting in the way now stated, severally produce other effects, when employed in hurtful quantities. Some of them excite certain of the organs concerned in excreting them from the circulation; others of them depress or exhaust the organic nervous influence and the irritability of the heart and other contractile parts; and many of them alter the constitution of the blood, especially of the red globules and fibrin, so as to render this fluid unsuitable to the perpetuation of the nervous and vital functions.

46. vii. *Numerous substances act especially upon the irritability of contractile parts, and either impair or increase this vital property, according to the nature of the substance.* These modes of action evidently result from the impression produced either primarily upon the organic nerves of the part, or consecutively upon the ganglia, the poison having been carried into the circulation, or from both these modes of operation. Prussic acid and the prussiates, monk's-hood, tobacco, aconite, digitalis, arsenious acid, colchicum, antimonials, borax, and boracic acid, ergot of rye, nitre, and several other substances, when employed in large doses, *depress* the organic nervous power, and the irritability of involuntary organs, especially of the heart, without directly impairing the functions of the brain and spinal cord, and of voluntary parts, although affecting them through the media of the ganglial and vascular systems. Other substances affect the irritability by increasing it at first and *exhausting* it afterward, the effect varying with the substance and the quantity employed. This operation probably obtains in respect even of some of the articles just enumerated, as arsenic and antimony. Other substances *excite* the irritability of both voluntary and involuntary organs more or less remarkably, as

nuxvomica and strychnia, brucia, St. Ignatius's bean, snake-wood, [the different species of rhus], &c.

47. viii. *Numerous articles act more especially in augmenting certain secretions and excretions; and they produce these effects either by their direct action on the organs to which they are applied, or by their consecutive operation, through the medium of the circulation, upon the organs and surfaces which they specifically influence.* Thus, emetics and purgatives taken into the stomach excite or irritate the organic nerves supplying the villous surface of the alimentary canal, and thereby increase the secretions and involuntary movements of the tube, each substance possessing either an emetic or a purgative property acting in a manner more or less peculiar to itself, and producing, moreover, in some cases, additional effects. Other substances, as many of those which act upon the kidneys, as the terebinthines, several salts, particularly the nitrate of potash, the nitrate of soda, the acetate of potash, cantharides or its active principle, and various other articles, are absorbed into the circulation, and excite especially the kidneys, so as to increase their secretion, or even to over-excite or inflame them. Other substances, through the medium of the circulation, affect the exhalations and secretions from the bronchi; and others, again, those from the skin. But this subject need not be farther pursued at this place.

48. ix. *That some articles irritate particular organs or parts in a way more or less peculiar to these articles, either when directly applied, or absorbed and carried in the blood to the organ affected by them, may be admitted.* But although this operation, and those just noticed, constitute the chief modes in which substances are expected to act medicinally—their principal therapeutical effects—yet they are merely subordinate to the more energetic or violent results produced upon the nervous influences and vital actions, when the same substances are employed in hurtful quantities.

49. x. *In connexion with this irritating operation, varying with the substance employed and the mode of its employment, an alterative action is also produced; the vital functions, the secretions, the sensible qualities and conditions, and the nutrition, of particular organs and parts being changed in kind or character, as well as dynamically or in degree.* These effects are manifested chiefly when poisonous substances are given repeatedly in small doses, are employed medicinally, or with the view of producing deleterious effects slowly and latently. Numerous medicines have acted injuriously in this way, as well as in the two preceding modes, in consequence of having been employed injudiciously; inappropriately as respects the nature of the disorder, and either during too long a period, or in too large or too frequent doses, the effects thereby produced having been mistaken for the progress of the disease. When substances have thus produced an alterative effect or change of action in any one or more organ or part, they have generally been absorbed to a greater or less extent into the circulation, and have operated, through the medium of the blood, on the tissues, or on the organs eliminating them from the system.

50. xi. *Substances which irritate or excite inor-*

dinately the parts or tissues to which they are applied, determine or solicit increased circulation and vital action to these parts, and proportionately diminish vascular action in distant parts, or in the viscera less intimately connected or associated in function with those on which these substances act directly. Many articles are employed medicinally with the intention of producing these effects, as *revulsives, derivatives, or revellents*; and many of the phenomena observed as consequences of poisoning depend upon this revulsive or derivative operation. This effect arises chiefly from the influence of the organic nerves, which, when irritated, influence the circulation in the associated capillaries and arteries, increase the vital expansion and action of these vessels, and augment the exhalations and secretions from them; the results varying, in kind and in grade, with the irritant or substance thus affecting the organic nerves of the part to which the increased action is thus determined.

51. VI. THE CIRCUMSTANCES WHICH MODIFY THE EFFECTS OF POISONS require to be briefly noticed.—(a) The *quantity* used materially affects the action of a poison, so much so that the most virulent poison is medicinal, or even salutary, when taken in minute doses. Thus prussic acid in a very small dose is soothing and antispasmodic, in a large dose it annihilates the vital action. Several poisons, in small quantities, slightly irritate or inflame the digestive canal, but in larger doses they produce convulsions, coma, and death.

52. (b) *The aggregation and degree of dilution* very materially modify the operation of a poison. The more minutely a deleterious substance is divided, and the more completely it is dissolved in oil or in water, the more energetically and the more rapidly it will act, especially when taken into the stomach. This necessarily follows from the preparation thus made for the action of the poison over a large surface, and for the imbibition of it by the tissues and absorption by the vessels. Certain substances, which are extremely active when thus prepared, remain for some time inactive when they have been taken in a concrete or aggregated state. The dissolving influence of the juices of the stomach, and of the secretions poured into the duodenum, is not without influence upon certain poisons, when taken in an undissolved state; for the carbonate of barytes and arsenite of copper are more soluble in these than in water. The operation of poisons is farther changed by aggregation and by degree of dilution. Camphor, in weak dilution, is cooling, sedative, and soothing; in stronger dilution in oil, or minutely divided in mucilage, it is exciting; and, in still larger quantity, productive of delirium, coma, or convulsions; and in fragments it may occasion inflammation, or even ulceration of the part to which it is applied. Certain poisons in a state of vapour, or even substances which cannot, in their usual states, be viewed as poisons, when employed in a state of vapour may become poisonous, if they be applied to extensive surfaces of the frame. Thus the inhalation of the vapour procured from numerous ascertained poisons, narcotics, and others; or of the vapour of ether, of alcohol, [of chloroform], and of certain volatile oils, when continued even for a short time, rapidly affects the frame, owing to the remarkably great extent of living

surface to which substances in a state of vapour are thus directly applied, to the extent of the impression produced by them on the organic nerves, and to their rapid absorption into the circulation.

53. (c) *Chemical conditions or combinations*, and the states in which chemical substances are employed, modify the effects produced. Some chemical substances, when employed in a concentrated state, act locally merely, as the mineral acids; but when taken internally in a state of weak dilution, they are carried into the circulation, and act upon and through the medium of the blood. Morphia, being insoluble, is comparatively inert, unless very minutely divided, but when dissolved in a fixed oil, or in alcohol, or combined with an acid, it becomes very active; and numerous substances which, in an uncombined state, are most deleterious, become innocuous when chemically combined with their opposites, as alkalies with acids, and *vice versa*. But this topic is so trite that I need not pursue it farther.

54. (d) *Admixture* of various substances, alimentary or others, either before or after ingestion, varies the effects; generally by diminishing the activity of the poison, owing to slow absorption and imperfect or intercepted contact with the villous surface of the stomach. If, however, the poison be taken in a state of complete solution, and if the substances taken with it, or those already present in the stomach, serve to dissolve or minutely divide it, they may not impede, but, on the contrary, ensure its action. If it be swallowed in a state of imperfect division or in fragments, the alimentary or other substances given with it may so involve these particles, or the mucus of the surface may so protect the organ, as either to diminish its effects, or to occasion vomiting, by which it may be altogether or partly thrown off. Dr. BOOTH has recorded an instance of an ounce of corrosive sublimate having been swallowed after a full meal, without any remarkably bad effects having been produced, full vomiting having been speedily induced; and other cases are referred to by Dr. CHRISTISON (see above, § 3).

55. (c) *The organ or tissue* to which a poison is applied has been already stated materially to influence its action on the economy, both locally and generally (§ 3–10). It has also been stated that the cuticle protects the skin more or less from the action of poisons, even the most corrosive and subtle; and it is not until it be removed or destroyed that the poison acts, or if it act, the effect is much more slowly produced. The mucous surfaces are much more readily acted upon: still the mucus and epithelium covering them protect them to some extent, and render them less susceptible of the poisonous impression, and less prone to imbibition and absorption, than serous surfaces, or denuded or incised parts. These latter parts, or wounds of any description, may, however, escape, if they bleed so freely as to wash away the poison. The rapidity of action varies much with the tissue to which the poison is applied, and is manifestly attributable to the celerity with which absorption proceeds in such tissue, and the extent of surface presented to the poison. Thus it is very rapid when a fluid poison is injected into the bronchi.

56. It is worthy of mention, as remarked, but

not explained, by Dr. CHRISTISON, that the poisons which seem to operate energetically on the sentient extremities of the nerves, and indirectly through the brain and spinal cord, act not at all upon the divided surfaces of the brain and large nerves, or upon the course of the latter; as proved in respect of prussic acid, opium, strychnia, and several narcotics. This circumstance may be partly owing to the mode of operation of poisons above contended for, viz., upon the organic nerves, or the organic and sensory nerves chiefly; the application of them to a cut portion of the fibrous structure of the brain, or of a nerve, not being likely to produce any farther effect than what may arise from the division of certain fibres of these structures. The effects of poisons on different parts depend much upon the vascularity and the disposition to imbibition and absorption possessed by the texture to which the poison is directly applied. The connexion also subsisting between the texture and the more vital organs, especially the dependence of the part upon the organic nervous system; the state of the vessels, the amount of hæmorrhage from them, and a variety of circumstances, also modify the results.

57. Mineral and vegetable poisons are much less controlled or influenced in their action by the organ or tissue to which they are applied than animal poisons are. The digestive canal and its secretions change the usual operation of mineral poisons but little; some vegetable poisons are somewhat more modified by the digestive organs in certain cases; but several animal poisons, which, if applied to a denuded surface, or to a wound, would be rapidly fatal, may be so altered by these organs as to be productive of but little disorder when taken internally.

58. (f) The operation of various poisons, especially of narcotic and sedative substances, is modified, also, by *habitual use* of them, and by *idiosyncrasy*. While use diminishes the poisonous effect, idiosyncrasy more commonly increases it. A person who has become addicted to opium, or even to some other narcotics, may take as much at once, with advantage, as would destroy the life of a person not accustomed to the substance; and a person may be almost poisoned by a substance, or an article of diet, as a particular kind of fish, that would not disorder others. The influence of habit, or use, is shown chiefly by the organic poisons, particularly those already mentioned. Inorganic or mineral substances have not their injurious operation so remarkably impaired by use. Dr. CHRISTISON supposes that this "effect of habit is nothing more than an increased power acquired by the stomach of decomposing the poison, just as it gradually acquires an increased facility in digesting some alimentary substances which are at first indigestible" (p. 29). This may be the case in part; but something is probably, also, owing to a gradually diminishing susceptibility of the impression produced by narcotics in the organic nerves, and of the nervous system generally, owing to their frequent exhibition.

59. (g) The *moral and physical states* of the system also modify the operation of poisons, especially of organic poisons, narcotics especially. Great mental excitement, anger, pas-

sion, &c., delay, or, to a certain extent, counteract the operation of narcotic and sedative substances, while the depressing passions hasten and ensure their effects. Several diseases, especially those of the nervous systems, as tetanus, rabies, mania, hysteria, &c., admit of large doses of opium, or of other narcotics, being given without injurious effects. Other substances, however, which are more sedative than narcotic, as tobacco, colchicum, prussic acid, &c., and which act more upon the heart, are not tolerated so manifestly during these diseases. Febrile diseases, especially during the stage of excitement and increased vascular action, delay or counteract in some degree the action of some poisons; while the same maladies, and more especially pestilential fevers and pestilential cholera, particularly during the stage of exhaustion, show that the frame is more or less insusceptible of the impression usually made by poisons. This want of susceptibility is owing to the low or exhausted state of vital function throughout the body, and to the absence of those vital conditions, or the commencing departure of these conditions, by means of which agents act upon living bodies.

60. Other diseases, or a predisposition to them, as to apoplexy, palsy, or congestive states of the brain, diseases of the heart, inflammatory states of the stomach or intestines, congestions of the liver, &c., may severally favour the operation of certain poisons, while these latter may excite or determine an attack of these maladies. Where there is an apoplectic or paralytic tendency, a small dose of a narcotic may occasion a serious effect, or even produce a seizure; and, when there is serious organic change in the heart, a large dose of a sedative, as of hydrocyanic acid, colchicum, or even a moderate dose, may terminate life. The irritant poison, which may be innoxious in some instances, may be fatal in others, where disease of the stomach or bowels, or a tendency to it, already exists; but this subject requires no farther illustration. It should also be kept in recollection that blood-letting, either soon after or before a poison has been taken, accelerates the action of such poison, if it remain in the part, by promoting its absorption.

61. VII. CIRCUMSTANCES WHICH SHOULD SUGGEST SUSPICIONS OF BEING POISONED.—(a) *The sudden appearance of severe symptoms while the patient is in health.* It is comparatively rare that a substance can be taken in an injurious quantity without almost immediately producing serious ailment. Without denying the occasional production of slow poisoning by the practiced poisoners of the Middle Ages, and of the succeeding two or three centuries, it may be admitted that this mode of poisoning was not so frequently attempted or accomplished as is generally supposed. At the same time, it should not be overlooked that poisons may be administered, as they sometimes have been, during the *illness* or the *intoxication* of the poisoned person, in order that the act may appear as the result of these states. The poison may even be added to the patient's medicine, or substituted for it, as has been shown on several occasions. Generally, the symptoms of being poisoned appear either immediately, or within an hour after the poison has been taken; and

it very rarely occurs that they are deferred beyond two hours, or three hours at the farthest. There are occasions, however, in which slow poisoning may occur unintentionally, and the symptoms be gradually and very slowly developed. I have met with several instances, in a somewhat long course of practice, of active and cumulative medicines having been given in large or frequent doses for so long a time as to produce dangerous, and even fatal effects; these effects having been mistaken, owing to the ignorance of the practitioner, for the progress and issue of the natural disease. Colchicum, digitalis, tobacco injections, opiate injections, tartar emetic, the preparations of iodine, and several other substances, have thus produced effects for which they did not receive the credit.

62. (b) *The appearance of severe symptoms after a meal, or after taking any substance, fluid or consistent, into the stomach, or after any substance has otherwise been exhibited or applied, should also be a source of strong suspicion.* What I have said above (§ 2-11), as to the several modes of poisoning, is sufficient to show that poisoning may be produced in various ways, besides the usual way of mixing the poison in the food or drink of the poisoned person. When, therefore, violent or fatal symptoms occur suddenly, or proceed rapidly, diligent inquiry should be made as to the time, nature, and kind of the patient's last meal, as to the circumstances and occurrences to which he has been exposed, as to the persons with whom he last had communications, and as to his habits and morbid tendencies. It should be kept in recollection that disease may exist, even for a long time, without occasioning suffering so great as to prevent his usual avocations; and that the stomach itself even may be the seat of disease, and yet a full meal may be taken, after which the most violent symptoms may supervene suddenly and carry off the patient. This is not an infrequent occurrence in cases of perforation of the stomach met with in practice, especially in young women (*see* *Stomach, Diseases of*). A fatal result, presenting the symptoms of poisoning, may also follow the ingurgitation of a large meal, or of indigestible substances, after long fasting, or of cold fluids when exhausted.

63. When several persons have partaken of the same meal, or of the same substances, as the individual who has been attacked with severe illness, the circumstance of the greater or less disorder of all, according as a particular article was partaken of, or the escape of any or of all, with reference to the meal generally, or to any particular article which it comprised, should receive due consideration; for, when all, or several of those who have partaken of the same meal, suffer more or less, the suspicion of poison amounts almost to proof, while the illness of one merely, others who had partaken of the same article not being affected, is a presumptive indication of the disorder being owing to other causes. In estimating, however, matters of this kind, the liquors and fluids drank, and the congruous nature of these, the one with the other, and with the several articles of diet also partaken of, should be taken into the account. Although it may be inferred that all who partake of the same poisoned dish will suffer according to the quantity partaken of, yet such is not always the case; for the

poison may be unequally mixed in the food; and, as respects certain poisons, especially those most frequently employed in this manner, as arsenic, a larger quantity of the poison may prove more innocuous than the smaller quantity; for the former may be vomited, while the latter may be retained and act most violently.

64. It ought to be recollected that various articles of diet may produce symptoms which may be more or less severe in all who have partaken of either of these articles, and these symptoms may depend upon the nature of the article itself, and not upon the admixture of any poison. Nevertheless, the article of diet is poisonous; but there is generally in this case no criminal poisoning; for the state and probable effects of the article are generally unknown, and not suspected by any one until the effects appear. Rancid bacon; unclean or improperly-fresh pork; dried or ill-cured meats and sausages; various kinds of fish, whether diseased or imperfectly cured, or kept too long; [cheese]; the flesh of diseased or over-driven animals; several kinds of shell-fish, [as oysters and muscles], especially when out of season; tainted or fly-blown meats, &c., are often productive of irritating and depressing, or acro-sedative effects, and have suggested the arrangement of these articles in the class of poisons which act in this manner.

65. (c) *The state of the patient's spirits or feelings previously to his seizure, and other matters which circumstances may suggest, should receive attention.* Acute observation and inquiry, exercised with due discretion and proper feeling by the physician, will often throw considerable light upon the origin and the agent of poisoning; will indicate either the accidental, the suicidal, or criminal nature of the act. The acumen required in such circumstances as present themselves in connexion with poisoning cannot be aided by what I can say on the topic; it will generally be sufficiently exercised by the well-educated practitioner of the present day; but the following should be more particularly observed, in all their relations, as upon them depend not only the recognition of the poisonous substance, but the treatment and life of the poisoned person, and the discovery and punishment of the guilty.\*

66. **MATTERS REQUIRING THE ATTENTION OF THE PHYSICIAN WHEN SUSPICIONS OF POISONING ARE EXCITED.**—When severe illness occurs in the circumstances just noticed, endeavours should be used to ascertain every particular as to circumstances and manner of its appearance. The vessel, utensil, or bottle, or paper which contained the injurious or suspected article; the remains of such article, whatever it may be, and of the food or drink which had more recently been taken; the matters thrown off the stomach, and the substances on which the sus-

[\* During the prevalence of malignant cholera in 1832, we mistook a case of poisoning by arsenic for an attack of this disease. A lady took more than a drachm of the arseniate of potash, as we afterward ascertained, with the intention of destroying her life; which was followed by severe retching, vomiting, cramps, lividity of skin, cold and clammy state of the surface, and the other symptoms which usually attended a severe attack of cholera. During the prevalence of this disease much greater caution will be necessary on the part of the practitioner, or he will be liable to err in diagnosis. The symptoms which attend a violent attack of cholera scarcely differ from those caused by the irritant class of poisons.]

peeted article has been spilt or rejected, should be carefully examined, in order to ascertain the nature of the poison; and, in cases of criminal poisoning, they ought to be preserved and chemically investigated, as fully set forth in works on *Medical Jurisprudence*. If death take place, the examination of the body as to position and external appearances should be minute; and the contents of the alimentary canal, and of the urinary bladder, as well as the digestive organs, and, in some instances, other organs also, should be carefully investigated, both anatomically and chemically, in order to ascertain the actual presence of the poison and the amount of structural change produced by it. Numerous other matters connected with the poisoned person, and with the appearances of the various objects around him, both before and after death, ought to be noted; but, as these have especial reference to judicial proceedings, I must refer the reader to medico-legal works, especially to what has been stated by Mr. TAYLOR in his "*Medical Jurisprudence*."

67. VIII. THE SYMPTOMS CAUSED BY POISONS cannot be duly considered until I treat of the operation of individual poisons. I may, however, remark, that the symptoms usually assigned to many poisons have not been observed with accuracy nor described with due precision; and that they do not in many cases admit of either accuracy or precision, as they vary with the dose of the poison, and with the circumstances shown above (§ 51, *et seq.*) to modify them more or less. It will be seen from the *arrangement* I have adopted in discussing the action of particular poisons, that I have attempted to take a more intimate view of the effects produced by them than has usually been taken, and to base upon these effects a classification which may aid not only the recognition of the injurious agent, but also the adoption of appropriate means for the removal of these effects. It must have been manifest to all who have observed the operation of poisons, that many acrid or irritant poisons do not produce nearly the same nor similar symptoms; that several substances which have been arranged as acro-narcotic poisons produce no narcotic effects, unless contingently; that vitally depressing agents have been classed with pure narcotics, the effects resembling narcotism sometimes observed being merely those of departing cerebral functions, and that the effects which have been imputed to local irritation only have been quite as much owing to change of function throughout the economy, or to extreme vital depression. M. ORFILA, who has devoted himself so ably and remarkably to the subject now before me, and has performed so many experiments with poisons on the lower animals, has certainly reduced the classes of poisons to a too limited number, and has erred in considering many of the symptoms, as well as of the lesions after death, to have been caused by the poisons experimented with, instead of viewing them as partly the results of the injury inflicted on the animals the subject of experiment. Other experimenters no less deserve the same imputation. When he as well as they inform us that certain poisons were given to dogs, that, in order to prevent their rejection by vomiting, the œsophagus was tied, and that, in addition to various lesions

thereby produced, the lungs were found congested or inflamed, can we be warranted in assigning the pulmonary lesion to the poison only? Is not some part of these or of other lesions observed owing to the injury inflicted by the operation or by the ligature on the nerves in the vicinity, or on those actuating the œsophagus or adjoining parts?

68. i. The more intimately and accurately the symptoms of poisons are observed, the more easily will they be distinguished from natural diseases; and it is of the utmost importance that the former should not be mistaken for the latter. The distinctions will be noticed in the sequel; but I may here state, that the features of *gastritis*, *enteritis*, *gastro-enteritis*, *peritonitis*, *bilious* and *malignant cholera*, the *several forms of colic*, *malignant* or *adynamic dysentery*, *internal strangulation of the intestines*, *strangulated hernia*, and *perforations of the stomach or intestinal canal* may be very closely simulated by poisoning with most of the substances classed under the heads of *acrid and corrosive*, *acro-sedative*, *acro-alterative*, and *septic poisons* (§ 106); the particular features of the assumed disease varying with the particular poison, the quantity taken, and the various circumstances already shown to modify its operation; and that *apoplexy*, *epilepsy* and *convulsions*, *diseases of the brain or spinal marrow*, *diseases of the heart*, *rupture of internal viscera* or of *large vessels*, and *spontaneous congestion of the lungs* may likewise be simulated by the operation of many of the poisons ranked under the classes *depressing* and *paralyzing*, *exciting* and *exhausting*, *narcotic* or *stupefying*, and *narcotico-acrid*, the particular or special effect varying according to the circumstances just alluded to.

69. From this it will readily appear that the difficulty of inferring, with any degree of accuracy, the particular poison which has been taken, from its effects only, is extremely great; and hence the necessity of obtaining farther information as to its nature from what may remain of the vehicle in which it has been taken or otherwise employed, from the matters vomited or evacuated by the bowels, and from other sources or circumstances. In examining the symptoms caused by poisons, care should be taken to estimate as accurately as possible the remaining vital and nervous energy of the patient, to ascertain by the hand and by the ear, or stethoscope, the impulse and energy of the contractions of the heart, to observe the manner in which position affects the state and feelings of the patient, as well as the pulse, and to distinguish between effects which are truly narcotic and those which are still more serious, viz., those proceeding from extremely depressed or departing vital manifestation of the brain. Equal care should be exerted not to mistake increased irritability for excitement or augmented power, and not to confound a very rapid or a very open and compressible pulse with consecutive inflammation, although inflammation may be actually induced, but it is of an asthenic or spreading kind when it thus appears; for these states of the pulse may arise merely from some degree of remaining irritation, from the alterations produced in the blood, or even from a portion of the poison still irritating the organic nerves and vascular system. In fine, care should be taken not to mis-

take the constitutional commotion consequent upon vital shock and exhaustion for sthenic or increased vascular action; and not thus be induced to deplete and lower the system, when we should calm its agitations and support its powers.

70. *ii.* THE DURATION OF POISONING necessarily varies with the virulence of the poison, with the quantity taken, and the repetition and frequency of the dose, and with the circumstances stated above as modifying the operation of poisons (§ 51, *et seq.*). Owing to these and a variety of other causes, appertaining either to the nature of the poison or to the state of the poisoned person, and to the effects more immediately resulting from a combination of these, poisoning may be, 1st, *acute or rapid*; 2d, *chronic or slow*.

71. *A. Acuteness or rapidity of action* is usually the result of the virulence and quantity of the poison; but, owing to the greatness of the quantity, the poison may be rejected by the stomach, and the expected result may either fail, or be more slowly produced. The state of the stomach, especially as respects the contents of the viscus, may also cause a similar issue, by absorbing much of the poison, and protecting the stomach from it.

72. *B. Chronic or slow poisoning* may result, 1st. From the lesion caused by a large dose of an active or virulent poison, which, although insufficient of itself to produce immediate or rapid death, owing to the above or other causes, is still sufficient to occasion changes leading, more or less directly and manifestly, to a fatal issue, *acute* thus subsiding into *chronic* poisoning; 2d. From the nature and quantity of the substance, which had been given in such a dose at first as to produce a slow but fatal effect; 3d. From the repeated ingestion of small quantities, which have gradually developed structural changes, or which, by their cumulative and latent influence, have ultimately burst forth into active operation. Illustrations of these several manifestations of the effects of poisons will appear in the sequel. Of the writers who have discussed the action, the effects, and the treatment of poisons, none has so judiciously marked the distinction between *acute* and *chronic poisoning* as Dr. PEREIRA, in his very distinguished work on the *Materia Medica*.

73. IX. THE GENERAL DIAGNOSIS OF POISONING.—The diagnosis of poisoning in the *living* and *dead body* is *general* and *special*. The former I shall briefly advert to; the *special diagnosis of poisons, or of poisoning*, requires a recourse to the most precise analysis, to chemical manipulations and chemical tests, and falls not within the scope of my undertaking.—i. *The general diagnosis of poisoning during life* has been partly considered in the preceding sections (§ 23–72), and it is more fully exhibited in the description of the several poisons about to be noticed; but farther evidence is to be obtained from the presence of poison in, or the absence of it from, the articles or fluids partaken of by the patient, and from the matters vomited by him. When poison is found in the matters vomited in the presence of a medical or scientific man, the proof of poisoning is much stronger than when it is found in the remnants of food partaken of; inasmuch as it is evident from this that the poison has actu-

ally been taken; whereas, in the latter case, it may have been put into the food with some sinister purpose, and not have been swallowed at all. Mr. TAYLOR justly remarks, that it should be recollected, while investigating a case of poisoning in the living subject, that this act is sometimes *feigned*, and at others *imputed*. It is very easy for an evil-intentioned person to put poison in food and to accuse another of having administered it, and to introduce poison into the matters, either vomited or discharged from the bowels. The detection of poison in the matters thrown off the stomach affords no decisive proof that it has been swallowed, except under two circumstances: 1st. When the accuser actually labours under the usual symptoms of poisoning; in which case there can be no feigning. 2d. When the matters are undoubtedly vomited into a clean vessel, in the presence of the medical man, or of some person on whose testimony perfect reliance may be placed; these matters never having passed from his view, from the moment of their rejection from the stomach until their analysis, examination, or due custody, under proper seals.

74. *A. The time at which death occurs after the first symptoms of poisoning* is of importance, inasmuch as death from natural causes rarely occurs in so short a time as from poisoning. Having ascertained all the circumstances connected with the attack, and all the symptoms manifested from the moment of attack until death, the exact time which has elapsed from the former period until the latter should be correctly estimated, as one of the elements for the formation of an accurate opinion as to the existence or non-existence of poisoning, and even as to the particular cause or agent of it. When a poison has been given in large quantity, the result may be supposed most likely to occur in the shortest time in which it is usually found to act. But the circumstances pointed out above (§ 52, *et seq.*) may delay its action or its ultimate effects. Poisons not only differ from each other in the period they take to produce a fatal result, but the same poison differs remarkably in this respect in different persons, although the several circumstances, as far as they may be known, appear to be nearly the same. Hence it is difficult to determine the shortest period in which a given poison will destroy human life, when swallowed in large quantity; and little reliance can be placed upon the circumstance of an imputed death from a certain poison having occurred too rapidly or too slowly, as a proof of its not having been taken; for an empty state of the stomach, the retention of the poison, and an exhausted state of the poisoned person will accelerate, and a full stomach and free vomiting will delay, the fatal result. On this subject Mr. TAYLOR states, that a large dose of strong *prussic acid*, *i. e.*, from half an ounce to an ounce, will destroy life in from ten to twenty minutes. In one case of this kind of poisoning, the particulars of which I had occasion to investigate, death must have taken place in about five or six minutes. If the person who is poisoned by this acid survive an hour, or even less, there are hopes of his recovery. *Oxalic acid* may prove fatal, in the dose of from half an ounce to one or two ounces, in a period varying from ten minutes to an

hour; and if the poison be not dissolved when swallowed, the period may be very much longer. The *strong mineral acids* destroy life, in large doses, in from twelve or sixteen hours to twenty-four hours. *Arsenious acid* usually is fatal, in periods varying from twelve hours to two or three days; but it may cause death in much shorter periods—in one, two, three, or four hours—an hour being about the shortest time. Mr. TAYLOR, however, remarks, that there is nothing to prevent arsenic from destroying life in one hour; and that, in a case which was most probably one of poisoning by arsenic, death took place in half an hour. The shortest time in which *opium* has been said to destroy life is three hours; but the period usually varies from six to twelve hours; but with it, as with all other poisons, the fatal issue may be protracted long beyond the limits mentioned of the more common period.

75. While the rapidity with which death from poison may take place is duly recognised by both professional and other persons, the fact that the same or other poisonous substances may occasion death slowly as well as suddenly, and even as slowly as the most chronic diseases, has not been sufficiently regarded, and the evidences connected with these effects have not been sufficiently, even if at all, investigated. There can be no doubt—and several instances of the fact have come under my own observation in the course of practice—of powerful medicines—of poisonous substances—having been too frequently or too long prescribed, in what was then considered full medicinal doses, now more justly estimated as dangerous quantities, and the consequences have been attributed to the progress of disease, to idiosyncrasy, or to other causes than the real. To those slow or chronic operations of poisons I shall advert when treating of individual poisons. It should not, however, be overlooked that disease of the heart and apoplexy may produce death as suddenly as a most virulent poison; and sometimes even more suddenly than any poison, with the exception of hydrocyanic acid. Death may occur almost instantly from organic disease of the heart, and but rarely within an hour from apoplexy, this acid being, perhaps, the only substance, unless in the very rare instances above noticed, which occasions death in so short a time; but, unless it be employed to commit murder, some traces of this poison are usually found at hand.

76. *B.* It may so happen that the *duration* of the symptoms is the only or the chief medical diagnosis of poisoning. In this case there must be both difficulty and uncertainty; and an opinion should not be formed without farther aids, although a careful review of all the known circumstances of the case, and of all the appearances about the person poisoned, may lead to very probable, and even correct inferences. In *acute poisoning*, or when life is rapidly destroyed, the diagnosis is generally more easy than in the *chronic*, or when death is occasioned by the consecutive effects of poison. But in many, even of the chronic cases, the cause of death is more or less manifest; as when a person who has swallowed a mineral acid, only partially recovers, and continues for many months afterward to complain of stricture of the œsophagus,

of which he ultimately dies. More frequently, however, it is most difficult to assign, with legal strictness, the ultimate result to the primary agent; to connect the fatal issue with the changes first produced by the poison, in cases of chronic poisoning; for numerous fortuitous influences or contingent agents may have intervened to re-enforce, modify, aggravate, or otherwise affect the earlier alterations, and thereby to subvert the regular succession of morbid phenomena from the first impression of the efficient cause until the fatal issue.

77. It is chiefly in a medical and strictly practical point of view that the slow effects of poisons—that *chronic and slow poisoning*—becomes interesting, and even most important: a form of poisoning altogether neglected by medical jurists, because rarely admitting of proof which may not be impugned. Corrosive sublimate, iodine, the arsenical solution, strychnine, digitalis, colchicum, and many other substances may severally be given in doses so large, or for so long a time, either with a beneficial or with a criminal intention, as to destroy life after a more or less prolonged period. In these cases the slow operation of the poison may occasion symptoms which may not be recognised as the effects of the medicine; or little or no effect may appear for a considerable period, until it suddenly breaks forth with such violence as to threaten, or even suddenly to destroy, the life of the person to whom the substance has been thus administered. But the effects may be both marked and characteristic of the poisonous substance prescribed, and yet be viewed as a part of the disease, and even identified with the disease which it was employed to remove. I hope, however, to direct a more especial attention to this matter in the sequel than it has hitherto received.

78. *ii.* The *diagnosis of poisoning furnished by post-mortem appearances* has been very ably considered by the recent writers on medical jurisprudence. Mr. TAYLOR, whose accuracy is generally commendable, remarks, that “in relation to external appearances there are none indicative of poisoning upon which we can safely rely. It was formerly supposed that the bodies of persons who were poisoned putrefied more rapidly than those of others who had died of natural disease; and evidence for or against poisoning was at one time drawn from the external appearance of the body. This is now known to be an error; the bodies of persons poisoned are not more rapidly decomposed, *ceteris paribus*, than those who have died a sudden or violent death from any other cause whatever.” (P. 42.) To the above too general and positive inference the following exceptions may be made: 1st. That external marks or changes may be left on parts of the external surface, as the mouth, face, neck, hands, and near the outlets of the natural canals, which not only may indicate poisoning, but even the particular substance employed, as several of the corrosive and irritant poisons. 2d. I have had proofs furnished to more than one of the senses—namely, to sight, smell, taste, and touch—that certain poisons, which I have classed under the head *septic and disorganizing*, actually produce a more rapid solution of the vital and physical cohesion of the tissues, or a more rapid progress of those *post-mortem* changes

either preceding or constituting putrefaction, than is usually met with, all the circumstances being otherwise the same. 3d. These senses have furnished me with evidence that certain poisons will sometimes delay these changes, at least in some parts, and even about the outlets of mucous canals.

79. *A.* The several *internal*, and especially the *digestive viscera*, however, are the quarters in which the physician should endeavour to ascertain the fact of poisoning, in defect or in aid of other evidence. The mouth, throat, œsophagus, stomach, and intestinal canal often furnish proofs of it, especially when acrid, corrosive, or irritant poisons have been employed; and although these proofs consist of the most severe lesions, and even of almost complete disorganization, they are often insufficient of themselves to show the particular poison which has been swallowed, or even the action of any poison at all, without proof of its actual presence, or other additional evidence, so completely do these lesions assume, in many instances, the appearances consequent upon certain natural diseases. Much of the difficulty of distinguishing the effects of poison from the consequences of disease is owing to the period which has elapsed from the time of death until that of making the examination; for during that period various *post-mortem* alterations supervene, which obscure certain of the more intimate changes existing at the moment of, or just previously to dissolution. Much of the softening, of the corrosion, or of the dissolution of tissues, found twenty, twenty-four, or thirty-six hours after death, has taken place during that period; and even the changes observed in the colour of the blood and of the several membranes and tissues, have chiefly occurred subsequently to death. In cases where the poison is of a virulent, septic, or of a chemical nature, as the strong mineral acids, or the alkalis, and when these have not been entirely thrown off during the short period of life following their ingestion, it may reasonably be supposed that the portion remaining in contact with the tissues will produce some change of the structures, even after death—will affect the dead textures as we perceive such substances to act in some of the operations of domestic economy, and either hasten or delay the solution of vital or physical cohesion, or otherwise change the appearance and condition of the textures by combining more or less intimately with them. In cases proving thus rapidly fatal, many of the poisons, especially the corrosive, the mineral, or saline, will be found either in the contents of the stomach or bowels, or in contact with the villous membrane of these viscera, or may even be detected by chemical analysis in the coats of the stomach, or even in the liver or in the blood.

80. Death, however, may take place suddenly, and various morbid changes may be detected in the digestive canal, resembling, or even identical with, those produced by certain poisons; but unless the poison be detected in the matters vomited during life, or in the contents of the stomach, or of other parts of the canal, or in the blood, or in the substance of the viscera, the evidence furnished by these changes alone is altogether inconclusive; for similar changes may occur about the time of

dissolution in cases of sudden death, or previously, or even subsequently to death, in various diseases not necessarily causing the confinement of the patient until shortly before, or even not until a few hours before death. To these alterations I now more particularly advert.

81. *a.* *Redness* of the villous membrane of the stomach and intestines is generally caused by acrid, corrosive, or irritant substances; but it is not of itself a sign of poisoning upon which much dependence can be placed, for it may be inconsiderable where corrosion and disorganization, caused by the most corrosive poisons, are the greatest; it usually characterizes all inflammatory diseases of the digestive canal, and it may be very remarkable in cases of sudden death from accident, external injury, or other causes producing fatal shock, and independently of any existing disease, or of the ingestion of any irritating agent, as shown by Dr. YELLOLY, and subsequently confirmed by numerous observers. It has been shown, 1st. That vascular congestion of the villous surface of the stomach, with a florid or dark-red hue, is not a proof of disease, and is not inconsistent with a state of health at the time of dissolution or shortly before it. 2d. That this state of redness and congestion, found in some cases after death, is not even proof of gastritis. 3d. That it is not alone an indication of the ingestion of a poison, or even of any irritant. 4th. That the vascularity of the villous membrane is an injection of the venous capillaries and veins, the redness depending, in the instances observed the soonest after death, upon the arterial character of the blood congesting the venous capillaries; and in those observed the latest after dissolution, upon the transudation of the colouring matter, or to the post-mortem changes.

82. *b.* It is obvious that *redness*, as well as *congestion* of the villous membrane of the stomach, is liable to various changes during the time elapsing from death until examination. These changes are not only such as take place in ordinary circumstances during this time, both in the blood itself and in the tissues, but those also which are more especially caused by the morbid impression of the poison by the treatment resorted to, and by the action, previously and subsequent to dissolution, of the poison upon the textures and upon the blood itself. When the redness is caused by poisons which not only irritate, but arrest more or less the putrefactive process, then it may be inferred to continue the longest after death. Mr. TAYLOR found it continue in the stomach and duodenum of the exhumed body of a man poisoned by arsenic, twenty-eight days after he had been interred.

83. *c.* *Ulceration* of the internal surface of the stomach is seldom observed in cases of poisoning, and never unless in those which have been manifested by well-marked symptoms previously to death. Ulceration is more frequently caused by arsenic than by any other poison, and this poison may even be found lodged in the edges of the ulcers, which present more generally the appearance of small circular abrasions of the villous membrane, which is more or less generally inflamed, or inflamed in the intervals between the ulcers, the inflammation sometimes extending to the duodenum and intestines. Ulceration from disease is not unusual

(*see* STOMACH, *Diseases of*); but in these cases the inflammation surrounds the ulcer, which often has tumefied or thickened margins, while the ulcers produced by poisons present different appearances. The history of the case before death will generally enable the physician to determine to what cause the ulceration should be imputed. But ulceration should not be confounded with *corrosion*. Ulceration, although a morbid, is also a vital process, in which the secretions, the nutrition, and the absorption of the part are disordered, consecutively of inflammation. Corrosion is a disorganization of the intimate structure by a chemical action, which destroys the vital properties, and dissolves the vital cohesion of the textures; the corroding substance combining more or less with the tissues upon which it acts. Ulceration requires time to produce it; corrosion takes place instantaneously or almost immediately (*see* more fully on this subject, DIGESTIVE CANAL, § 36, *et seq.*).

84. *d. Softening of the inner surface of the digestive canal* is a frequent effect of poisons, and is often found associated with corrosion, but is more diffused. Softening may be often viewed as merely a lesser grade of corrosion, especially when it extends to the several coats. It is generally most remarkable in the stomach, but, when it is limited to this organ, it cannot be considered as a consequence of poisons unless the inference be supported by farther evidence, inasmuch as it is, when thus limited, most commonly the result of disease. When it is caused by poisons, corrosions of some parts often accompany it; and the softening is frequently extended from the fauces down the œsophagus, into the stomach and duodenum. This change should, however, never be considered as a result of poison, unless the poison be detected in matters which have been vomited, or in the contents of the digestive canal, or in the coats of this canal; for it is, even when thus extended, a very frequent result of disease, more especially in infants and children.

[In this connexion, it should be borne in mind that softening of the gastro-intestinal mucous membrane, especially that portion lining the stomach, is very frequently met with in intemperate subjects; indeed, it is the most common pathological change met with in such cases.]

85. *e. Perforation of the digestive canal* is sometimes found, upon dissections, after the ingestion of poison, but it is also not unfrequently a consequence of disease. When caused by poison, it is commonly merely the extension of corrosion through all the coats of the viscus, and is most frequently found in the stomach, but it occurs in rare instances, also, in the duodenum and œsophagus. Perforation, like all other alterations of the digestive canal, although preceded by symptoms of poisoning, is not a proof of this act, unless the other proofs just noticed be also present. When it is a consequence of disease, it is produced by ulceration, which rarely or never occurs in cases of sudden or rapid poisoning, ulceration being the result of a morbid process requiring some time for its production; but this topic will be noticed in the sequel (§ 114), and it is fully discussed in the article DIGESTIVE CANAL.

86. *f. The villous coat of the stomach may present other lesions which may furnish stron-*

ger evidence of poisoning than any of those already noticed. These are *corrugation*, *partial detachment*, *dark discoloration*, resembling *charring*, of the villous membrane; *ecchymosis*, or *small extravasations of dark, coagulated blood*, underneath this membrane, which is raised into small elevations, and a *dark-red or livid engorgement of the capillaries and veins*. These changes are most frequently found in the stomach; but they are sometimes seen, although in a less marked degree, in the duodenum, and even in other parts of the intestinal canal.\* Some degree of *induration* of the villous membrane of the stomach has been found in some cases after poisoning with sulphuric acid.

87. *g. A post-mortem change*, which has been variously denominated, and especially as *spon-taneous softening*, *pulpy degeneration*, and *spon-taneous perforation* of the coats of the stomach, is met with upon dissection, in rare instances. When this alteration is found in a patient who evinced no indications of gastric disease during life, and when it is unattended by any inflammatory appearances, the coats being gelatinous or pulpy, it may then be viewed as a consequence of the action of the gastric juices after death, as first stated by JOHN HUNTER, and rendered probable by the more recent researches of CARSWELL, BURNS, SHARPEY, and others. But a nearly similar change may be the result either of poisons or of disease. In the former case, which will be more particularly noticed hereafter, evidence of poison will generally be found either in the organ itself, in its contents, or in the matters vomited; and, in the latter, gastric disorder will have been manifested previously to dissolution, and the pulpy softening or perforation will be accompanied with some indications of inflammatory irritation, although in the aphthous, mesenteric gastric, and gastro-enteric diseases of children, and more especially of infants, about the period of teething, weaning, and, when improperly fed, softening, and even perforation of the stomach will occasionally be found, inflammatory appearances either not existing, or, if they have existed, having altogether disappeared soon after death. (*see* DIGESTIVE CANAL, § 35, 42).

88. *iii. The other means of diagnosis*, so frequently adverted to above, namely, *the detection of the poison by chemical analysis and tests*, and the support which *moral circumstances* may afford the evidence, belong more especially to the medical jurist.—*A. The moral circumstances and appearances*, falling under the observation of the physician, should always be carefully remarked by him, not only as they may suggest to him the existence of poisoning, and thereby direct his attention to every point and aspect of the case, but also as they may be required from him in the judicial investigation, in which he will appear as a principal evidence. In every instance admitting of the least suspicion of poisoning, it is the duty of the medical man to ascertain as fully as in his power the whole range of symptoms or morbid phenomena; to observe assiduously the progress of the symptoms, from the moment they came under his notice until their termination in recovery or in death; to obtain information from those best

\* All these appearances result from the habitual use of distilled liquors, and when met with, the habits of the individual should be closely investigated.]

able to furnish it, as to the circumstances connected with the origin and progress of the seizure; to trace their origin in obvious or imputed causes; to connect them, as far as may be done, with such causes as usually produce similar effects, and to determine, as far as possible, the presence of such causes in the case in question; and, if death take place, to note carefully all the changes observed in the dead body.

89. The importance of care and circumspection in these matters is shown by the fact that, although instances often occur in which the diagnosis of poisoning cannot be established, unless the poison be actually detected, to the satisfaction of the tribunals, still it may be sufficiently so to warrant the physician in the adoption of such measures as the symptoms will suggest for the recovery of the patient. And it should be recollected that, even in the event of death, there are many poisons which, owing to their nature, cannot be detected by any analysis or test, while there are others quite susceptible of analysis, which may be so changed or mixed with substances, alimentary and others, as to escape detection by chemical agents, either in the vomited matters, or in the contents of the viscera, or in the blood. In many such cases, there may be satisfactory proof of the persons having been poisoned, and, in some, conviction has actually followed, although the poison has not been detected in the dead body; the symptoms, the appearances after death, and the moral circumstances being sufficient to establish the fact. Moreover, due attention to every circumstance connected with the history and progress of the case, as insisted on above (§ 61-72), will enable the physician to ascertain, even during the life of the patient, the particular poison employed, or, in default of this, the class of poisons to which it belongs, and to adopt a plan of treatment, which, if not successful, may nevertheless be appropriate to the symptoms and circumstances of the case. In the event of death, also, he will be more surely directed in his search for the substance which caused it, and his analysis and tests will be chiefly suggested and guided by the changes which the *post-mortem* examination will disclose.

90. B. As soon as suspicions of poisoning are excited, or indications of it evinced, the *portions of the substance* which has produced the symptoms should be sought for on the persons of the poisoned and of the suspected individual; and if the substance cannot be found in the pure state, or in that of mixture with other substances, a chemical analysis should be instituted of the *several articles, fluid and consistent, of which the patient last partook*; and this inquiry should be full and satisfactory; for one portion of a dish may be poisoned, and not the other; the gravy, and not the meat; the sauce, and not the fish; the pie-crust, and not the fruit, &c., &c. The salt may contain arsenic, and nothing else at table may contain this poison; and so on as respects various articles, and as regards several poisons. *The matters vomited, and those evacuated from the bowels, the former especially, should be chemically examined, or tested, as soon as possible, and during the life of the patient, whenever there is doubt as to the nature of the poison, in order that the treatment may be as appropriate as possible;*

but as tests, and a chemical laboratory, cannot be carried about with the physician, the physical appearances and characters of the matters thrown up should be carefully observed, in connexion with the history of the case, and the existing symptoms, and the treatment directed accordingly. The vomited and evacuated matters ought, however, to be carefully preserved for chemical analysis, and those thrown off the stomach should be compared with the *matters found in the stomach and intestines after death*. These matters, with the digestive canal itself, and often with the collatitious and other viscera, should then be made the objects of chemical research, in order to satisfy the ends of justice. But this subject does not fall within the scope of this work.

91. X. DIAGNOSIS OF POISONING DURING DISEASE.—This is a topic which has been slightly adverted to above (§ 59, 60) as one which has received but little attention from medical writers, and which hardly admits of satisfactory elucidation.—(a) *Poisoning, either criminal, accidental, or suicidal, while the poisoned person is the subject of disease, or under medical treatment*, has occurred oftener than has been commonly suspected. Poisoning in these circumstances has certainly been attempted, and even accomplished, much more frequently than it has been detected, owing, 1st. To the difficulty of determining the symptoms during life, and the changes after death, which belong respectively to disease and to poison; 2d. To the facility with which a poisonous substance may be added to, or substituted for, the patient's medicine, without suspicion being excited; 3d. To the symptoms caused by the poison being mistaken for the severity and progress of the disease; the previous duration of illness and other circumstances preventing any inquiry as to the cause of death; and, 4th. To the circumstance of the poison which has been employed not admitting of chemical detection, either from its nature, or from the state of admixture or combination in which it has been taken. The difficulties in forming a correct diagnosis when a person is poisoned, in the course of disease, is heightened by the acuteness and severity of the malady; and when a poison has been administered whose operation is such as closely to resemble, or as to appear, an aggravation of the symptoms of which the patient had complained, then the diagnosis can hardly be established, unless by the detection of poison in the matters vomited or in the evacuations from the bowels or kidneys, or in the body after death.

92. (b) When a patient is suffering from diseases of *debility*, or is labouring under *exhaustion, anæmia*, the effects of *losses of blood, and chronic discharges*, poisoning is more readily effected, especially by depressing, paralyzing, and acro-sedative substances, than in other circumstances; and the effects, especially when the poison has been administered in successive doses, or at intervals, are not readily recognised or distinguished from the progress of the malady. In these states, also, of the patient's health, more especially when hæmorrhage or vascular depletions have preceded the ingestion of poison, absorption of it into the circulation more readily and more injuriously takes place, and the patient furnishes much less of vital resistance to its fatal operation.

93. (c) I have had several reasons to believe, from the history of cases, &c., that poisoning has been both attempted and accomplished in the *puerperal states*, especially during the first two or three weeks after delivery; the operation of the poison having been mistaken for one or other of the diseases incidental to that state; and having been such as not to be distinguished from such disease unless by the discovery of the poison, aided by various moral considerations.

94. (d) *Acute diseases of the digestive canal and associated organs* may have existed for a longer or shorter time, and irritant, acro-sedative, or corrosive substances may be administered accidentally, criminally, or from ignorance, which may so aggravate the attack as to render it dangerous or fatal. The heroic practice of medicine, so general and so much lauded, even within the range of my own observation and recollection, by those who concealed their ignorance by the swaggering boast of being "practical men," and that the literature and science of medicine were beneath their notice, as they were certainly beyond their reach, has furnished me with several proofs of actual poisoning having been committed by those self-sufficient and illiberal mediceasters in the treatment of the diseases just mentioned. I have often seen, and had still more frequent occasion to remark, in medical writings, the recommendation of the most irritant purgatives, in excessive doses, in cases of enteritis, or in dysentery, with the intention of removing obstructions, or of expelling matters which had no existence, the substances prescribed either causing inflammation, or increasing that which already existed, and urging it on to a fatal issue. Irritant, corrosive, acro-sedative, or acro-narcotic substances, given either in poisonous quantities, or in so frequent doses as to become poisonous, in the course of these maladies, could not readily be recognised by their effects in these circumstances, nor even by chemical research, if the employment of them were concealed, and the mischievous tendency of their operation were not known.

95. (e) Even in *chronic diseases* of the alimentary canal, especially *chronic dysentery*, or the *chronic diarrhoea* of warm climates, the exhibition of repeated doses of acrid purgatives, or of other medicines, with erroneous views of the nature of the case, and of the operation of the substance prescribed, has converted a complaint by no means serious into one which has become rapidly fatal. I have seen this practice in various places, and I could adduce numerous cases in which it has been recorded in published works, or in the case-books of hospitals, furnishing useful, although fatal, beacons in navigating the shoals of medical practice.

96. (f) Persons already the subjects of *diseases of the heart or of the lungs* may be cut off by a criminal, or an incautious use of various sedative, acro-sedative, or acro-narcotic substances, especially when taken in too frequent doses, or continued for too long a time. Digitalis, tartar-emetic, colchicum, aconite, &c., may be given in these diseases so as to produce a fatal result, without the symptoms being suspected as being caused by poison, or the result being viewed otherwise than as the *natural termination of the disease*; and the examination

of the body after death, and chemical research, will fail of discovering the cause. From 1810 until 1830—a period abounding with medical cant, heroic and empirical practice, and disgusting dogmatism—certain substances came into very general use, from the abuse of which much mischief accrued, even within the sphere of my own observation; calomel, tartar-emetic, colchicum, digitalis, and, more recently, iodine, were often given in such excessive doses, or continued in smaller quantities for so long a time, as to induce more serious diseases than those for the cure of which they were resorted to. The natural maladies had the efforts of nature to aid them, if these efforts had been developed or duly directed; but the substances which were employed subverted vital energy, suppressed the natural efforts, produced morbid actions and organic lesions, which were mistaken for the course or turn of the primary malady; and, when they failed of causing death, occasioned a new or different form of disease. A patient had disease of the valves of the heart and dropsical effusion; large doses of infusion of digitalis were prescribed to act as a diuretic, and this effect was sometimes produced, and a certain amount of ease resulted; but quite as frequently the disease was arrested in a different way; the action of the heart was so much weakened by this treatment as to become insufficient to overcome the obstacle to the circulation, and death was the consequence. Early in the present century, colchicum and tartar-emetic were lauded as antiphlogistic remedies, as they certainly are, and were often brought in aid of the copious blood-lettings and various other empirical means unduly lauded by the ignorant pretenders and writers of the day. More than one writer of great but ephemeral popularity extolled these substances, and prescribed them in excessive doses for the inflammatory and other diseases of the lungs and bronchi, both of children and adults; and I am confident that, in the former class of patients more especially, they were employed in such quantities, and for so long a time, as to prove fatal to more than they cured. The vital resistance, which so successfully opposes the progress of disease in most instances where there is no constitutional vice, was completely overthrown by these and similar means; and while vitality was either suppressed, impaired, or altogether destroyed by them, no opposition could be furnished to the unfavourable progress and consequences of the disease.

97. This subject might be pursued with reference to the diseases of other organs, and to various constitutional and febrile maladies; but I have, perhaps, stated what may be more than sufficient to rouse the attention of those who are not sufficiently aware of the importance which ought to be attached to it; well-educated, closely observing, and, in virtue of these, the only experienced practitioners, hardly require to be reminded of the several matters which these suggestions will undoubtedly recall to their recollection. Any further notice which this subject may require, will be taken of it in the discussion of the effects and treatment of individual poisons.

98. XI. THE GENERAL PRINCIPLES OF TREATMENT.—What I have advanced will show the importance which should be attached to the

operation of poisons, as forming the basis of rational measures of prevention and cure. Before I proceed to notice the injurious operation of particular poisons, and the treatment which each appears to require, I shall first offer a few remarks upon certain intentions and principles of treatment, which are more or less generally applicable, according to the mode of poisoning which has been resorted to. These brief remarks will refer to the *prevention*, to the *counteraction*, and to the *removal of the effects of poisons*.

99. *A. Prevention of the action of poisons* may be attempted in certain circumstances, and may succeed either partially or completely. A poison may be swallowed, and, if the means be immediately resorted to, it may be removed before it has acted, or acted to a very injurious extent. —(a) The means of removal are *emetics* and the *stomach-pump*. Of the former, but little may be said more than that they often fail to act, owing to the paralysis, or want of power of contracting, experienced by the parts concerned in the act of vomiting from the action of the poison which has been swallowed. It is, therefore, requisite to give powerful and warm emetics, as the sulphate of zinc, with capsicum, mustard, &c., according to the nature of the poison which has been taken; the intention being to excite the organic nervous influence at the same time that the discharge of the poison is procured, when this latter is of a sedative or narcotic kind.

100. (b) The removal of the contents of the stomach by means of an apparatus, such as that now in general use under the name of *stomach-pump*, although suggested by several persons long before the practicability of such means was actually put to the test, was first demonstrated, as being efficacious in cases of poisoning, by Messrs. Jukes and Scott in 1822, then medical practitioners in Westminster; and, in many instances, it is the most efficient and certain mode of removing the poison; but it is liable to certain objections. The perforations in the end of the tube may be obstructed, or the canal of the tube choked by the alimentary substances present in the stomach, and the withdrawal of the contents and of the poison will be thus delayed or even prevented, if fluids be not injected into the stomach by this tube, in order to remove the obstruction and dilute the contents of the viscus. In cases, therefore, in which imperfectly dissolved poisons have been taken, or where a greater activity may be imparted to the poison by dilution or solution, the recourse to injections may be injurious, and the use of this apparatus may be less efficacious, in these circumstances, than an active emetic, which often empties not only the stomach, but the duodenum also, and increases the secretions of the villous surface and of the liver, thereby washing off the adhering portions of the poison, or preventing the imbibition and absorption of them. When, however, a judiciously-prescribed emetic fails to act, or in cases in which an emetic may be inferred to be inactive, or in other doubtful circumstances, recourse to the stomach-pump should not be a moment delayed.

101. The removal of the poison is an indication which is not confined to cases in which the substance has been swallowed. It is equally

important in instances of *external poisoning*, the object being the prevention of the imbibition and absorption of the poison. There are two modes by which this intention may be accomplished: 1st. The application of a ligature above the part which has been inoculated with the poison, or between it and the trunk, so as to arrest its absorption and contaminating influence, and the diffusion of its impression by means of the nerves. This mode of prevention has been in use from the earliest ages, and is practiced by most savage tribes. It is obvious, however, that this practice would be inefficacious if nothing farther were attempted, and that the poison would act as soon as the ligature was removed. The great advantage of the ligature is to delay the operation of the poison until it can be either generally or partially removed by suction, or counteracted by local applications and internal remedies. Many substances are poisonous when applied to the skin denuded of its cuticle, or when inserted in a wound; and may yet come in contact with the mucous surface of the lips and mouth without risk, if there be no abrasion of the epithelium: and hence *suction* of a poisoned wound with the mouth, after the application of a ligature, where this can be applied, or suction without this antecedent in other circumstances, has been resorted to from the earliest ages, and is still practiced in all uncivilized countries. The ligature, by arresting the return of blood, while arterial action increases the capillary injection, and even augments the discharge from the wounded surface, thereby favours the removal of the poison by suction, or by any other mode of exhausting the air over the part which may be adopted.

102. The intention of removing the poison introduced into a wound by exhausting the air over the wounded part was strenuously contended for by the late Sir D. BARRY; and for this purpose he advised the application of the *cupping-glasses*; and in situations where a ligature cannot be applied, cupping-glasses are the best means of sucking out the poison, or the blood and serum contaminated by the poison, from the part. But not only is absorption thus prevented, and the poison withdrawn, but the injurious impression made by the substance on the nerves of the part is prevented from extending, owing to the pressure produced by the margins of the glasses. We have certainly not improved in modern times upon the treatment of poisoned wounds recommended by the ancient Greeks, Romans, and Arabians, as Mr. ADAMS has fully shown. NICANDER, CELSUS, DIOSCORIDES, GALEN, and nearly all the Arabians, advise the application of a ligature, and then the extraction of the poison by sucking, by cupping instruments with scarifications, cauteries, escharotics, &c. They likewise prescribed remedies with the view of altering or counteracting the effects of the poison. If the poison was of a depressing kind or produced cold, they resorted to stimulating and heating medicines; if it was of an opposite nature, they gave refrigerants; but they most frequently had recourse to articles of a heating nature, as they believed that the greatest part of poisons destroyed life by producing cold.

103. *B. The counteraction of the operation of the poison* is the next indication; and it often suc-

ceeds in respect of some, especially if attempted soon after the poison has been swallowed or applied; and the substances which thus counteract the poison have been called the *antidote*, or *counter-poison*. The antidotes of some poisons, especially of some mineral poisons, are well ascertained; and it is chiefly to chemical science that we are indebted for this knowledge; but we know but little of the means of counteracting many other poisons, especially those of the vegetable and animal kingdoms. Those antidotes whose actions have been ascertained are, 1st, those which form chemical combinations with the poison that are not injurious, as alkalies with acids, &c.; and, 2d, those substances which deprive acrid and corrosive poisons of their properties, or which form insoluble compounds with the poison. Certain antidotes are complete and efficient, if administered sufficiently early, or before organic or vital changes of a dangerous nature have been produced; others are only partially efficacious, as ammonia in cases of poisoning with prussic acid.

104. Means which enable the system to resist the action of a poison may be ranked in this category. Those which prevent the absorption of the poison, as several of those which have been already noticed, or such as counteract the depressing influence of certain poisons, as the spices, cayenne pepper, aromatics, spirituous liquors, &c., in cases of animal or fish poisons, are often more or less efficacious. When poisons are taken in large quantities, the economy, especially the nervous system, sustains more or less of shock; and, if appropriate means be immediately used to aid it in rallying, a greater degree of vital resistance will be opposed to the progressive advance of the effects. From these remarks, it may be inferred, that in our endeavours to counteract the operation of a poison, we should attend to the following cautions: 1st. To avoid all means which may render the poison more soluble, or which may dissolve it, or add otherwise to its activity; thus we should not give wine or vinegar soon after a large quantity of opium has been taken. 2d. To avoid such measures as may promote the absorption of the poison into the circulation, as blood-letting. 3d. In cases of poisoning by depressing agents and narcotics, or such as destroy nervous power and irritability, medicines, emetics or others, which act in a somewhat similar manner, as tartar emetic, ipecacuanha, &c., should not be exhibited. 4th. That the shock sustained by the ingestion of virulent poisons should be counteracted by energetic means of a stimulating and restorative kind, administered according to the peculiarities of the case; and that vomitings, however frequent, should not prevent the exhibition of these, in cases of narcotic, depressing, and animal poisons, or even in others, unless the vomitings proceed from the action of corrosive and very acrid poisons.

105. *C. The removal of the progressive effects of the poison, and opposing the tendency to death*, remain to be put in practice either when the first and second intentions cannot be attempted, owing to the time which has elapsed from the exhibition of the poison, or after one or both have failed. To be successful in these circumstances, the physician should be well acquainted with the physiological action of poisons, and with the phenomena by which this

action, in its progressive phases, are indicated; with the symptoms and progress of the mischief; and with the pathological states produced by individual poisons, and more immediately inducing death; he should be acquainted with the operation of active substances on the economy, both in medicinal and in poisonous doses, in order that he may duly recognise the nature and effects of the latter doses, and may apply the former to the removal of these effects, according to rational indications. That a knowledge of the physiological and pathological actions conjoined, consequent upon the exhibition of a poison, and of the ultimate changes of which death is the result, is of the utmost importance to the physician, is evinced by the fact that it is this very knowledge which, in extreme cases, and after other indications and means have failed, enables him to devise farther measures which may still be successful. Thus, if it be ascertained that the poison, in the advanced course of its effects, has produced paralysis of the muscles of respiration, or spasm or closure of the glottis, means directed to the continuance of respiration, or the production of artificial respiration, may yet save the patient. This fact has been demonstrated on several occasions, and other analogous illustrations of the principle will appear in the sequel. It is obvious that nothing farther can be advanced with due precision under this head, until the effects of the individual poisons are considered.

106. XII. CLASSIFICATION OF POISONS.—The effects, and the ultimate results of poisons being so diversified and complex—many producing nearly similar or variously modified effects, and the same substance evincing very different phenomena in different persons and circumstances, the effects of a single poison being thus neither constant, nor always distinctly developed—it follows that a satisfactory classification of them can hardly be expected. Indeed, all attempts at classification must be conventional; for if we endeavour to arrange them conformably with their physiological action, or according to the systems or tissues on which each appears especially to act, we shall find, as must be manifest from what I have already advanced, that many of them act upon, or through the media of, two or more systems, and upon several functions; and that the substance which affects one person, or one system, in a more or less definite manner, operates differently in others, the effects varying with the circumstances shown to modify the operation of poisons (§ 51, *et seq.*). Although we should have regard to the succession of changes consequent upon the ingestion of a poison until the ultimate results appear, still we have here comparatively little concern with those which follow the employment of the same substance in small or medicinal doses. It is the deleterious action which should be observed, and the best means of counteracting that operation, and of averting or removing its usual effects. The question is not whether or no opium, morphia, or hydrocyanic acid, &c., be stimulants, sedatives, or narcotics, or entitled to other appellations which have been given them; but it is practically, to which of these properties, or to what other property, are the injurious effects chiefly owing, and by what successive changes are these ultimate effects pro-

luced? It is principally the progressing and advanced alterations of vital function or of structural lesion that are to be arrested and remedied, and it becomes most requisite that we should not only know the nature of these changes, their whole extent, and their probable issue, but also that we should arrange those substances which operate in similar or nearly similar modes, and induce similar results, in order that the treatment which may be found successful against one poison belonging to this category may be advantageously extended to the others. That an arrangement of poisons should be adopted according to this principle, with reference to the operation and effects of these agents, and that the classification may thus be made practically useful in a therapeutical point of view, is shown by the extension by the author of the affusion of cold water on the head and neck to cases of poisoning by various narcotic and sedative poisons. The cold affusion had been employed for ages for intoxication and insensibility caused by inebriating liquors; and the author, having repeatedly seen it thus employed with success, had recourse to it in 1821, in a case of poisoning by *opium*, published in 1822 in the *London Medical Repository* (vol. xviii., p. 29), and in 1825 he recommended, in the work now named (vol. xxv., p. 40), this practice in cases of poisoning with *prussic acid*, and with other poisons belonging to the same classes as those just named; and this treatment has been found most efficacious in states of vital depression and insensibility produced by narcotics and sedatives generally. The propriety, therefore, of adopting a classification based upon the most prominent operation and effects of individual poisons, as being the most practically useful, must be apparent. In venturing to recommend an arrangement different from that which has been suggested by Dr. PARIS, and from that advised by FODÉRÉ, and adopted, with certain modifications, by ORFILA, and still further modified by CHRISTISON, DEVERGIE, BECK, TAYLOR, and several other recent writers,\* I have been influenced chiefly by the firm conviction, entertained without any doubt from the first enunciation of these classifications, that they were inadequate and inaccurate; inasmuch as the principal operation and effects produced by several virulent poisons had no place given them, or did not fall within the scope of the arrangement, and as various substances were classed under heads to which they could not with due accuracy be assigned, and were hence viewed

as productive of effects of which they were altogether innocent, while those which they did actually produce were not at all, or not sufficiently recognised. Thus prussic acid and the prussiates were arranged in the class narcotics, and numerous substances were classed as irritants, whose operation in this respect was the least considerable of the several effects produced by them. From the observations made above as to the general and special operation of poisons on the animal economy (§ 28, 34, *et seq.*), the following classification is suggested as corollaries: i. *Acrid and corrosive poisons.* ii. *Depressing and paralyzing, or sedative poisons.* iii. *Exciting and astringent.* iv. *Exciting and exhausting poisons.* v. *Irritating and depressing or paralyzing—acro-sedative poisons.* vi. *Irritating and alterative—acro-alterative poisons.* vii. *Narcotizing or stupefying poisons.* viii. *Narcotizing and irritating—narcotico-acrid poisons.* ix. *Septic or disorganizing poisons—dissolving the vital cohesion of tissues.*

107. As to these classes, I may remark, that the operation of the substances arranged under the first is more or less strictly local, when the quantity of either is large, or when the poison is concentrated; but that when certain of these substances are employed in small doses, or in weak solutions, they will then act in such a manner as may warrant the arrangement of them under different heads. The third and fourth classes might have been comprised in one and divided into two orders, but I considered it better to have too many classes than to subdivide them. I may offer the same remark as to the fifth and sixth classes, but for practical purposes I preferred the arrangement as it stands.

108. XIII. OF THE SPECIAL EFFECTS AND TREATMENT OF POISONS.—CLASS I. ACRID AND CORROSIVE POISONS.—*The irritant poisons of several recent authors.* The numerous substances arranged by recent writers as irritants, comprise many which I have here denominated and expressed more strictly in accordance with their real operation. It surely cannot be admitted, moreover, that the substances which I am about to consider under this class destroy life by merely irritating the surface to which they are applied. Is there no local lesion produced beyond irritation? That the local action amounts to something far beyond irritation will be admitted by every one who is in the habit of observing closely, or of attaching precise meanings to words. The want of precision is here chiefly owing to the circumstance of these writers having classed under the same kind those substances which are most acrid and corrosive, and most limited in their sphere of action, with others which are really but slightly irritant, and which are destructive of life by producing other and very different effects from irritation. This will become more apparent in the sequel.

109. i. OF THE SYMPTOMS AND DIAGNOSIS OF POISONING BY ACRID AND CORROSIVE SUBSTANCES.—The symptoms vary with the degree of solubility, the concentration of the solution, and with the nature and admixture of the substance. When the poison is very soluble or is fluid, and very corrosive, the mouth and tongue evince most severe symptoms; there are burning and pricking or darting pain, redness, swelling with exudation of lymph, or corrosion and destruc-

\* The arrangement proposed by Professor FODÉRÉ was as follows:

i. Septic poisons. ii. Narcotic or stupefying poisons. iii. Narcotico-acrid. iv. Acrid or rubefacient. v. Corrosive or escharotic. vi. Astringent poisons.

ORFILA at first adopted, with slight modifications, the above arrangement, but afterward reduced the classes to the following:

i. Irritants. ii. Narcotics. iii. Narcotico-acrids; and, iv. Septic poisons.

CHRISTISON, BECK, and TAYLOR have adopted this arrangement of M. ORFILA, discarding most undeservedly the class septic poisons.

The classification suggested by Dr. PARIS is based upon the presumed mode in which individual poisons act.

i. Poisons which act through the medium of the nerves without being absorbed, and without exciting local inflammation. ii. Those which enter the circulation, and act through that medium with different degrees of force, on the heart, brain, and alimentary canal. iii. Those which act locally on the mucous membrano of the stomach, exciting a high degree of inflammation.

tion of the mucous membrane or epithelium, and an acrid and burning sensation in the mouth and fauces. These sensations and alterations extend more or less to the pharynx, and along the œsophagus; and the patient is incapable of swallowing, or, if he attempt to swallow, the matters are spasmodically rejected. When the poison is fluid, as a mineral acid or an alkali, the burning pain and change of structure rapidly produced in the mouth, throat, and œsophagus, and all the symptoms referable to those parts, precede disorder of the stomach; and in some instances the poison is not conveyed farther than the œsophagus, owing to its violent action on the pharynx, and the spastic contraction of this part and of the upper part of the gullet. When, however, owing to the peculiarities of the case, or to the less solubility or state of admixture of the poison, the mouth and throat are but little or slightly affected, the stomach then evinces the chief disturbance. Pain, sickness, or nausea, burning heat, and vomiting, are rapidly produced. In some instances the burning pain and acrid constriction extend from the mouth or pharynx, along the œsophagus to the stomach. The pain and vomiting follow immediately upon the passage of the poison into this viscus. The rejected matters consist at first of the contents of the stomach, with more or less of the poison, and subsequently of mucus and serum, often streaked with blood and mixed with bile, but frequently also altered by a portion of the poison being conjoined with them. Owing to the rapid rejection of its contents, and of the greater portion of the poison, the stomach may be chiefly or almost alone affected. This is the case, however, in comparatively rare occasions, for some of the poison most commonly passes into the duodenum, and often also into the small intestines, especially when the poison, as arsenic, is not very soluble, or is taken in an undissolved state; and in these circumstances some time may elapse between the ingestion of it and the occurrence of vomiting. But when this or any other poison is taken in such quantity and state as to produce a corrosive effect, the action on the stomach is manifested very soon after its ingestion; and is attended by more or less tenderness, tension, and soreness in the upper regions of the abdomen, and by a terrified or an anxious expression of countenance.

110. When an acrid or corrosive poison reaches the intestines—which may not occur when the poison is very active, and the lesion of parts above the pylorus is intense, and the shock to the vital endowment consequently great—most acute burning or lacerating pains more or less constant, but aggravated at intervals, are felt around the umbilicus or over the whole abdomen, and are attended by a sensation of twisting, sometimes by a feeling as if the intestines were drawn against the spine, and often by a distressing aching in the loins extending to the epigastrium. The abdomen is always tense and tender, but at first there is no swelling, but rather a retraction of the parietes; but distention from flatus generally supervenes. Purging is frequently present with tenesmus, and sometimes with excoaration of the anus. After feculent matters are passed the stools are mucous, watery, or serous, streaked with blood, or contain a considerable quantity of

blood. The affection of the bowels may be the prominent effect, the stomach being comparatively but little disturbed; but more frequently the whole alimentary canal is affected, and vomiting and purging, with distressing pain and vital depression, are present at the same time.

111. As the operation of the poison proceeds painful and scanty micturition occurs; hicough sooner or later appears, and becomes distressing; the pulse is rapid, small, and weak; the strength and spirits are prostrated, the features sunk, the surface is covered with clammy cold sweats, the extremities are cold and shrunk, and the voice fails. In cases where the poison excoarates the fauces, pharynx, or upper portion of the gullet during deglutition, the irritation often extends more or less to the epiglottis and glottis, producing wheezing or difficult respiration, hoarseness, or spasm of the glottis, and, in rarer instances, even death by asphyxia. It will appear from this that this class of poisons produce effects which may readily be mistaken for several of the diseases mentioned above (§ 68); and to the diagnosis between these effects and those diseases I shall next briefly advert.

112. A. CERTAIN LESIONS OF THE STOMACH are attended by symptoms, especially near a fatal termination, very closely resembling those produced by corrosive substances.—(a) *Rupture and partial laceration of the stomach* may follow sooner or later after a full meal, and owing to the circumstance, as well as to the attendant phenomena, occasion suspicions of poisoning, which, however, an examination of the body after death readily disproves. Instances have occurred of persons who have eaten too largely, either after long abstinence, or after having suffered from dyspeptic disorder, and who have been seized with violent but ineffectual attempts to vomit, pain in the stomach, sudden collapse, and death in a short time, preceded by abdominal tumefaction and tenderness. On dissection, laceration of the coats of the viscus and the passage of the alimentary matters into the peritoneal cavity have been found. In the case described by M. LALLEMAND, which occurred after long privation and dyspeptic symptoms, the patient exclaimed that she felt her stomach tearing itself open. The laceration was five inches long; the coats were not diseased, but the pylorus was indurated. Dr. CHRISTISON refers to two cases in which the laceration appeared to have been caused by the accumulation of gases arising from depraved digestion. In these, as well as in cases where the distending matters have been more consistent, the laceration has been owing as much to weakened vital cohesion of the coats of the stomach as to the amount of the distending matters. Instances of rupture of the stomach have been recorded by Dr. ROBERTS and Mr. WEEKS; and upon dissection no sufficient cause of the occurrence was detected. It may be, therefore, inferred that flatulent distention of the stomach having occurred, as it usually does, when the vital tone and cohesion of the organ are most impaired, spasmodic reaction or contraction of the parietes had taken place, during which laceration had been the result. The rupture may be only *partial*; as in the case related by Mr. CHEVALIER, where the symptoms of corrosive poisoning occurred after a very full meal, at-

tended by vomitings of blood towards its close. Upon examination after death, the inner coat of the stomach was torn in several places, and that of the duodenum was also extensively lacerated.

113. (*b*) *Rupture of the coats of the stomach at the bottom of a chronic ulcer, or perforation of the stomach*, may be attended by similar phenomena to those caused by corrosive poisons. 1st. The ulceration may have existed and been attended by paroxysms of pain, or of retchings, and when it had proceeded as far as the peritoneal coat, or partially through the muscular coats, the distention of a full meal, or of flatus, in connexion with efforts at vomiting, has produced *rupture of the tissue forming the bottom of the ulcer*, and the escape of the contents of the viscus into the peritoneal cavity. 2d. The ulceration may have gone on to *perforation* without any evidence of rupture or laceration. Perforation may, however, take place without the escape of the contents of the stomach into the peritoneal cavity; the peritoneal surface around the perforation having become agglutinated to an adjoining viscus, as in two cases which occurred in my practice.

114. *Perforations of the stomach* are described in the articles DIGESTIVE CANAL (§ 36-43) and STOMACH; it is, therefore, only necessary to state at this place, that the symptoms attending them in their course, and towards their fatal termination, should be carefully distinguished from poisoning; for the diagnosis is not always easy. Perforation occurs most frequently in females between 16 or 17 years, and 25 years of age, especially in the scrofulous diathesis, in the sedentary, and in connexion with disordered catamenia, and in delicate or weak constitutions. The severe symptoms, especially sudden and acute pains, retchings, or vomitings, anxiety, vital depression, &c., generally occur after eating or drinking, and especially after a full meal; and, if perforation has actually taken place, there is always vital shock or collapse, accompanied by the extension of pain and tenderness, with more or less tumefaction or tension, over the whole abdomen. In these cases, the advanced symptoms and death are results of the peritonitis caused by the matters which have escaped into the peritoneal cavity; and the vomiting is often slight, consisting chiefly or altogether of articles recently taken. There is seldom purging, which frequently accompanies poisoning, although constipation is not so generally observed as stated by some writers. The appearances found after death, and a careful examination of the articles partaken of, and of the matters thrown up, are the chief means of diagnosis.

115. *B. LESIONS OF THE INTESTINES AND ALLIED PARTS* may be attended by symptoms resembling the action of corrosive poisons.—(*a*) *The duodenum*, as well as the stomach, may be ruptured, independently of external violence, without any other apparent cause than overdistention, and retchings while in this state. Dr. CHRISTISON refers to an instance of a man who was seized after dinner, when mentally excited, with violent pain in the stomach, vomiting, and failing pulse, soon followed by death. The mucous surface of the duodenum was much inflamed; and, four inches and a half from the pylorus, a laceration extending through a

third of the circumference of the bowel was observed.

116. (*b*) *The passage of gall-stones*, and the violent pain, vomitings, and vital depression accompanying this affection, may suggest suspicions of poison; but the slowness of the pulse, or the absence of febrile symptoms, the tolerance of pressure in the region of the stomach, or the presence of jaundice, will, in some instances, indicate the nature of the case. Still these symptoms cannot be relied upon, and they may not be present; other circumstances duly investigated furnishing the chief sources of diagnosis. Besides, gall-stones may produce severe irritation, with abdominal or epigastric tenderness and tension, as well as pain and vomiting; and when these occur soon after the ingestion of food or drink, they furnish sufficient reasons for careful observation and examination on the part of the physician. An elderly lady, after slight jaundice, was suddenly seized with violent pain in the stomach, vomitings recurring in frequent fits, followed, after some hours, by most excruciating pains, incessant retchings, coldness of the skin, and failure of the pulse. In seven hours from the fresh accession of suffering she expired. The hepatic duct was found torn across, a gall-stone at the opening of the cystic duct, and three pounds of blood and bile in the peritoneal cavity, which was inflamed in different parts. (*Journal des Prog. des Sc. Med.*, t. xiv., p. 245).

117. (*c*) *The sudden flow of acrid bile into the duodenum*, especially during warm seasons, after this secretion had accumulated in the gall-bladder and ducts, is not infrequently the cause of symptoms which have been mistaken for the ingestion of acrid poisons. This is most likely to occur where a person who is subject to this biliary accumulation takes some article which disagrees with him, or some cholagogue purgative. I have met with two or three instances of persons who complained of the symptoms I have described as diagnostic of biliary accumulation or obstruction (see GALL-BLADDER, § 18, *et seq.*, and LIVER, § 48, *et seq.*, and § 78, *et seq.*), and for whom a moderate purgative dose was ordered. But the medicine having removed the obstruction, the passage of acrid bile into the duodenum occasioned symptoms of so violent a nature—retching and vomitings, diarrhœa, pains in the stomach and throughout the abdomen, &c.—as to suggest suspicions of an acrid or corrosive poison having been given, instead of the medicine prescribed. The bile which passed into the duodenum in these instances possessed sufficient acidity to occasion many of the symptoms of poisoning.

118. (*d*) *Bilious cholera* may likewise be mistaken for the effects of acrid or corrosive poisons; indeed, it is most difficult in many cases to distinguish between them, and still more difficult to point out any means of diagnosis which can be depended upon. Much will depend upon the acumen of the physician, and the view he takes of the history of the case, and all the circumstances attending it. The nature of the ingesta, and the state of the matters ejected, should be carefully inquired into; and if heat, acidity, or darting pains be felt in the mouth, pharynx, or œsophagus, their occurrence *before* or *after* the vomiting ought to be ascertained.

and the mouth and pharynx should be examined. These symptoms seldom even attend, and never precede bilious cholera; while they very frequently, indeed most commonly, precede poisoning with acrid or corrosive substances. Blood is never seen in the matters thrown from the stomach in cholera, whereas it is frequently seen in these matters when the vomiting has been caused by these poisons. Bilious cholera, or any state of cholera observed sporadically in this country, even when excited by indigestible articles of diet, rarely terminates fatally within 48 hours, and, indeed, very seldom thus terminates even in a much longer period, whereas the effects of corrosive poisons are much more rapidly fatal.

119. (c) *Pestilential cholera* is also liable to be mistaken for poisoning with acrid substances; but the same circumstances as have been just noticed serve to distinguish between them, with the exception of the rapid termination of the former, which is frequently equally rapid with the latter. But the prevalence and infectious nature of this pestilence, the general symptoms, the state of the surface and of the extremities, and the appearances and odour of the fluids thrown off during the progress of the malady, will readily distinguish it from poisoning, especially if the physician have seen cases of it on any former occasion.

120. (f) *Inflammation of the stomach, or of the intestines, or of the peritonæum*, may be confounded with poisoning with corrosive substances, the first of these more especially. Acute gastritis, uncomplicated with inflammation of an adjoining viscus, seldom occurs primarily in temperate climates, and not very frequently in warm countries, unless as a consequence of the excessive use of spirituous liquors or other stimulants; but it does occur more frequently both in England and Scotland than Dr. CHRISTISON has inferred from the statements of M. Louis. Acute gastritis sometimes is produced primarily—and formerly it was produced more frequently—by drinking excessively of spirituous liquors, and the severity of the symptoms were occasionally such as to equal the violence of those occasioned by acrid poisons; but the history of the case, the symptoms of intoxication, the odour and appearances of the matters rejected, &c., will sufficiently point out the nature of the affection. It must be admitted that the possibility of acute gastritis being produced by natural causes is a question of great interest and importance to the practical physician. Dr. CHRISTISON remarks, that the possible occurrence of this disease, independently of poison, is the only obstacle in the way of a decision in favour of poisoning when, in cases characterized by signs of violent irritation during life and early death, bright redness, ulcers, and black granular, warty extravasation are found in the internal surface of the stomach; and in regard to their effects he adds, that they can very rarely indeed arise from natural causes, or, indeed, from any other cause than poison. Admitting the truth of this, I may state, that violent gastritic symptoms, death after some hours, with vascular injection, redness of the inner surface of the stomach, and numerous ecchymoses, have occurred, without sufficient evidence of poisoning, unless, in some instances, the excessive use of spirituous

liquors be considered as such, and to which it is strictly entitled. When ulcers, excoriations, abrasions, or corrosions of the inner surface of the viscus are found, in cases which have terminated rapidly, and in connexion with bright redness, ecchymosis, &c., there can be little doubt of the ingestion of an acrid or corrosive poison, although it may have escaped detection. An important sign in cases of gastritis, as well as of cholera, is the absence of excessive heat or burning in the throat, or of painful and difficult deglutition; which very frequently precede the vomiting in cases of poisoning by acrid substances, and which seldom attend and never precede the vomiting from spontaneous gastritis or enteritis.

121. (g) *Acute enteritis, gastro-enteritis, or peritonitis*, may, in some instances, give rise to suspicions of poisoning; and the physician will consequently be induced to inquire, as in the diseases already noticed, 1st. As to the time at which vomiting appeared after a meal, or after the ingestion of any article whatever. 2d. As to whether the disease was ushered in by chills or rigours, or is attended by febrile reaction or commotion. 3d. As to the state of the bowels, of the evacuations, and of the matters thrown off the stomach. 4th. As to the symptoms referable to the mouth, throat, and œsophagus. 5th. As to the presence or absence of diarrhœa, and of excoriations at the anus; and, 6th, into all the circumstances connected with the history and existing state of the case. The causes assigned for the attack; the relations subsisting between these causes, and the supervention of chills or rigours, of vomitings, and of consecutive febrile reaction; the existence of constipation, and the absence of lancinating pains or burning sensations in the mouth, throat, and œsophagus at the commencement, and of painful and violent purging and excoriations of the anus at an advanced period, with other particulars connected with the history of the case, will distinguish most instances of spontaneous inflammation of the digestive organs and of the peritonæum from poisoning with acrid or corrosive substances.

122. (h) *Perforation of the intestines*, as well as perforation of the stomach, always terminates fatally; and when it is attended by symptoms simulating those which are caused by acrid poisons, an examination after death will show the nature of the case. (See DIGESTIVE CANAL, § 40, *et seq.*, and INTESTINES, § 80, 81.)\*

123. (i) *Colic, iliac passion, and strangulated hernia* may severally be mistaken for poisoning with corrosive substances, especially when they are attended by violent retchings or vomiting; or poisoning by these substances may be mistaken for these. *Internal strangulation, intussusception of a portion of intestine*, and the existence of *intestinal concretions*, or other causes of obstruction, may likewise occasion symptoms closely resembling poisoning, especially the vomitings, pain, anxiety, and vital exhaustion attending them. But the history of the case, the obstinate constipation, the appearances and odour of the matters thrown off the stomach; the sensations of the patient as to the seat of obstruction and pain; and the lesions found after death, with the other cir-

\* This statement is too broad; perforation of the intestines, though generally, is not always fatal.]

cumstances already adverted to, will serve to distinguish these maladies from the effects of poisons.

124. Having taken a view of the features distinguishing certain natural diseases from the effects of corrosive or acrid poisons, I should now proceed to describe the *structural lesions* produced by these latter; but as these lesions differ very remarkably from each other, according to the particular substance causing them, I shall briefly notice them in connexion with the especial consideration of the several substances acting chiefly by their corrosive or acrid properties, or by the *local changes* produced in the viscera, with which they are brought in contact; and for facility of reference, I shall treat of them in alphabetical order.

125. *i. ACIDS.*—*A. ACETIC ACID*, in its concentrated state, *acts* chiefly as a corrosive agent. Although, in its various forms, it is in daily use, it is rarely the cause of death, even when swallowed by mistake in considerable quantity. Its injurious effects have been described by ORFILA, BARRUEL, SCHUBARTH, and HÉBRÉART.

126. *a.* According to the last-named experimenter, a small quantity of acetic acid dropped into the *windpipe* occasions difficult and hissing respiration, croupy cough, and death in two or three days, the surface of the larynx and trachea being covered with a false membrane similar to that found after croup.

127. *b.* The concentrated acid, *applied externally*, acts as a corrosive agent on the tissues. In this state it operates chiefly locally, dissolving the albumen, fibrin, and gelatin; and is but slightly absorbed. It coagulates, and renders dark the blood in the capillaries.

128. *c.* If *injected into the veins* in a strong or concentrated state, or if the quantity be considerable, it changes the physical appearances of the blood, and alters the colour and condition of the red globules. According to Dr. POMMER, when it is dilute, or about the strength of the distilled vinegar in common use, several ounces of it may be injected into the blood without material mischief; but the more recent experiments of ORFILA throw much doubt upon this inference.

129. *d.* Acetic acid *taken into the stomach* in large quantity, but more especially in a very concentrated state, and if the stomach be empty, produces agonizing pain, and a sensation of burning in the stomach, with anxiety at the epigastrium, and convulsions, and death after a few hours. In this concentrated state it acts chiefly locally, and is not absorbed in an appreciable degree. It affects violently the nerves of the organ, the affection being propagated to the large visceral ganglia; and it coagulates the blood in the capillary vessels of the organ, and arrests the circulation through them, occasioning also a vital shock. In dilute states and in frequent doses, this acid acts chiefly through the medium of the blood, lowering nervous energy and vascular action, as will be shown hereafter. (See next CLASS.)

130. *e.* The *appearances after death* by the concentrated acetic acid are, lividity of the integuments of depending parts of the body; a brownish and leathery appearance of the mouth, fauces, and pharynx; and a similar change extending down the œsophagus to the stomach or to parts of this viscus. The inner surface of

the œsophagus presents large patches of a dark-brown hue, with reticulations of injected capillary vessels. The stomach, in some places, has a grayish tint, interspersed with dark-redish spots, with numerous ecchymoses, and several large, black elevations, consisting chiefly of coagulated blood in the sub-villous cellular tissue. A livid or black hue of the fundus or near the pylorus; a thick, dark, pulpy matter adhering to parts of the internal surface of the organ; and the presence of more or less of the acid in this viscus or in the intestines, have also been observed. The intestines are not materially altered.

131. *f. Treatment.*—Draughts containing calcined magnesia, or the alkaline or magnesian carbonates; the cautious use of the stomach-pump, as the villous surface of the œsophagus and stomach is readily injured by mechanical agents after corrosive poisons; the injection of magnesian or alkaline solutions, and the removal of the contents of the viscus soon afterward by this apparatus, are the measures more immediately required. Subsequently, albuminous or demulcent fluids, mild broths, arrow-root, sago, and various mucilaginous and farinaceous articles of diet, may be given in small quantities, and frequently.

132. *B. THE HYDROCHLORIC, THE NITRIC, AND THE SULPHURIC.*—As these acids, usually denominated the *mineral acids*, when used in poisonous states and quantities, produce similar phenomena, and require the same means for the counteraction and removal of their effects, I shall consider them under the same head, and, in some respects, in connexion. *Hydrochloric acid—muriatic acid—spirit of salt*—is not infrequently employed as a poison; but the *nitric acid—aqua fortis*; and the *sulphuric acid—vitriolic acid—vitriol—oil of vitriol*, are not infrequently resorted to, for purposes of murder or suicide, or of external injury short of murder. Either of these acids may be swallowed by mistake, or be employed in various criminal ways. TARTRA adduces an instance of a female who, having been intoxicated, was poisoned by nitric acid, which was mixed with wine and poured down her throat. A woman was convicted of murdering her husband by pouring sulphuric acid down his throat while he lay asleep with his mouth open; and several instances have occurred of the same acid having been given in poisonous doses, in place of the medicines which had been prescribed. The mineral acids, especially the sulphuric, have likewise been employed, by abandoned persons, to poison their own infants; but they are much more frequently resorted to as a means of suicide. They have also been employed, from motives of revenge or of dislike, to disfigure the countenance or person; the concentrated acid being squirted or thrown over exposed parts of the body. Mr. TAYLOR states that the external application of nitric acid has been a criminal cause of death on many occasions. In one instance this acid was poured into the ear of a person while sleeping, and it led to the slow destruction of life.

133. *a.* The *symptoms* occasioned by the mineral acids, *when swallowed in a concentrated form*, are of the most violent description, but the alterations produced by them on the organization are chiefly local and structural. Dr. CHRISTI-

son justly remarks, that they afford the purest examples of true corrosive poisons, their poisonous effects depending entirely on the organic injury they occasion in the textures to which they are applied; and that it is of use to set out, in the investigation of the effects of poisons, by determining the phenomena presented under such circumstances. I shall have more immediately to describe the violent symptoms and the severe structural change produced by these substances before a fatal result ensues; and in the sequel to show the much less violent phenomena, and the very slight local signs which other poisons hitherto classed with these leave of their operation, and yet prove more rapidly and certainly fatal than they; and few will fail of being struck by discovering the great extent of lesion the animal frame will sometimes endure from the former—the most violent of all corrosive substances—and yet recover; and the very slight alterations locally produced by these other poisons, whose operation is so rapidly fatal. These circumstances will of themselves prove sufficient to warrant an arrangement in which substances differing so very materially in their local and constitutional effects as those alluded to should not be classed, as they hitherto have been, under the same head, but should be arranged under different classes, according to their most prominent mode of operation and effects.

134. *b.* The mineral acids may produce fatal effects when *applied externally*, when *injected into the veins or into mucous canals*, when *inhaled in the form of fumes*, and when *swallowed*. When *applied externally* in a concentrated form, or even in a state of strong dilution, they irritate, corrode, or inflame the skin. The nitric, or rather the strong nitrous or fuming nitrous acid, produces these effects most severely; but the sulphuric and hydrochloric act almost as violently as it. In the stronger states these acids chiefly act locally and disorganize the tissues, the coagulation of the blood in the capillaries and the destruction of the organization on which they act generally preventing their imbibition and absorption.

135. *c.* When *injected into the veins*, even in a state of considerable dilution, they coagulate the blood, and thus destroy life; but when the dilution is still greater, or such as to allow of the circulation and presence of either of these acids in the vessels of the heart, ganglia, or brain, before coagulation even partially takes place, it may reasonably be inferred that the vital manifestations of these organs will be thereby rapidly subverted.

136. *d.* If the fumes of either of these acids, or any of the gaseous forms which they assume, either singly or in states of admixture with other gases or vapours, be inhaled, the most severe effects on the respiratory passages and lungs are produced. When either nitric oxide gas, or nitrous acid vapour, hydrochloric acid gas, chlorine, or sulphurous acid, in more or less strong states, is attempted to be inspired, spasm of the glottis is produced by it, and its entrance into the respiratory organs is thereby prevented. In a weaker form, either of these acid vapours may pass into the lungs, but it irritates and inflames the mucous surface of the larynx and trachea, the inflammation extending along the bronchi to the air-cells and lungs, pro-

ducing dangerous or even fatal laryngitis, bronchitis, or pneumonia, or a complication of these. Several instances are on record of persons having been destroyed by the violent and extensive inflammation of the respiratory surfaces produced by these fumes, and by the nitric oxide gas converted into nitrous acid vapour by mixing with the atmosphere.

137. *e.* The injection of either of these acids into mucous canals with a criminal intention has been rarely recorded. But an instance is published in the *Medical Gazette* (vol. xvii., p 623), abridged from a French journal, of sulphuric acid having been given in an enema by mistake for oil. As soon as the enema was injected, the patient uttered distressing screams, passed the night in the utmost agony, and died in the course of the following day. Numerous instances have been published of the murder of children with sulphuric or nitric acid, chiefly the former, which has generally been poured into the mouth or throat. When poisoning is effected in this way, the acid may not reach the stomach; it may not even get farther than the pharynx or upper portion of the œsophagus. Being poured into the mouth or throat of the child when asleep, or when crying or struggling, a portion of it irritates the epiglottis, or even escapes into the glottis, occasioning strangulating cough, and asphyxia by closure of the glottis, with violent inflammation or disorganization of the pharynx and adjoining parts, as observed in some cases when acid has been swallowed accidentally.

138. *f.* When either of these acids, or an admixture of these acids, has been swallowed, the effects vary conformably with the circumstances mentioned above (§ 51, *et seq.*). These effects have been most ably investigated by TARTAR, with reference more especially to nitric acid, which, as well as the sulphuric and hydrochloric, may be employed for the purposes of suicide, or of murder, or may be swallowed accidentally. However taken, with whatever motive, or in whatever quantity or degree of concentration, the acid may not, especially when taken accidentally, reach farther than the pharynx or œsophagus, its acidity, the violence of its effects, or the discovery of a mistake arresting deglutition before any portion of it could have reached the stomach. Nevertheless, fatal results may rapidly ensue owing either to the extensive disorganization of textures in, and adjoining to, the pharynx, or to the inflammation or corrosion of the larynx, the tumefaction of these parts closing the glottis, and either causing or threatening asphyxia. In these cases, although the acid may not reach farther than the upper part of the œsophagus, the effect upon the larynx may be so violent as rapidly to produce suffocation, if tracheotomy be not performed. M. TARTAR considers that the mineral acids produce effects which may be arranged as follows: 1. Speedy death from violent corrosion and inflammation. 2. Slow death from a peculiar organic change of the stomach and intestines. 3. Imperfect recovery, the person remaining liable ever after to irritability of the stomach. 4. The recovery of perfect health; but the operation, by means of asphyxia, caused in the way now stated, should be ranked as a fifth mode or variety.

139. *g.* The most common symptoms are those

of the first of these varieties, namely, burning pain, and acrid acid taste in the mouth, extending to the throat; extreme heat and pain between the sternum and spine, extending to the epigastrium and stomach, where it is most excruciating, and attended by extreme anxiety, by most painful or impossible deglutition; and an increase of these on attempts to swallow, on pressure, and on coughing. Eructations often take place from the stomach, and aggravate the sufferings of the patient, especially in the situations just named. The lips are commonly shrivelled, and are, at first, whitish, and afterward yellowish, if nitric acid have been taken; and brownish, if sulphuric acid. Excoriations or corrosions, but rarely blisters, are sometimes observed on or about the lips, or on parts of the skin with which the acid may have come in contact, as the cheeks, neck, breast, or fingers; and these marks undergo the same change of colour as observed in the lips and mouth. The inside of the mouth and of the cheeks is also more or less shrivelled, white, or corroded; and the teeth often in a very few hours become loose, brown, or yellowish-brown. The colour of the tongue varies with the acid, and the time which has elapsed from the application of the acid; but it is often yellowish, or yellowish-brown. Deglutition is so difficult, that attempts to take fluids are followed by the forcible rejection of them by the nose, the pharynx being spastically contracted. The matters vomited are generally brownish or black; and if they fall on marble or limestone, they produce effervescence. Afterward they are mixed with altered blood, and with membranous shreds, which resemble portions of the villous coat of the stomach, and sometimes actually consist of these, but most generally of coagulated mucus. The bowels are obstinately constipated, and the urine is scanty or suppressed. The abdomen, especially its upper regions, is tender and swollen. The pulse is very weak, and, toward the close, very small, imperceptible, or intermitting. It is seldom very frequent, and it may even continue but little or not at all accelerated throughout. The countenance, at first expressive of anxiety, pain, and distress, soon becomes collapsed, pale, and the extremities cold or clammy. The breathing is laborious, is often attended by singultus, and the movements of the diaphragm increase the pain of the stomach and epigastrium. In many cases the irritation and swelling in the pharynx and epiglottis, or even in the larynx, cause fits of suffocative cough, with croupy respiration, and, where the larynx has been more particularly injured, suffocation may not merely be threatened, but actually produced.

140. In some instances, especially when the quantity of acid which has passed into the stomach has been large, the symptoms may be less excruciating, but more rapid; while in others there may be a deceitful tranquillity, and life may be somewhat longer sustained. Thus, in the case adduced by TARTRA, of a woman who had been intoxicated, and was poisoned by aquafortis mixed in wine, although there were both pain and vomiting at first, yet none of these symptoms were afterward complained of, death taking place within twenty hours; but the intoxication probably obscured the sensibility, while the admixture with much wine modified

the operation of the poison. The intellectual faculties generally remain unimpaired to the last. Should the patient survive the first effects of the poison, the nuncous membrane of the fauces, pharynx, or œsophagus may be detached and discharged in irregular shreds, or in portions of considerable size, or even in a perfect cylinder.

141. *h. The duration* of this variety of corrosive poisoning may vary from two or four hours, as in the cases recorded by REMER and SINCLAIR, to two or three days; but life may be prolonged to ten or fifteen days. The usual period is from twelve to forty-eight hours. Death may be caused altogether by asphyxia, owing to the closure of the larynx, [the acid not reaching the stomach]; and if tracheotomy be resorted to, life may be thereby prolonged, as in the case recorded by Mr. ARNOTT; but death more frequently results; the structural change, the violent impression made upon the nerves, the vital shock, the coagulation of the blood in the vessels of the parts with which the acid came in contact, and the local arrest of the circulation and of the associated vital functions, combining to produce the fatal issue. [In these cases death generally results very speedily, often within a few minutes.]

142. *i. The quantity* of a mineral acid capable of producing fatal effects cannot be stated with any precision, as the result depends upon the several circumstances stated above (§ 51, *et seq.*) Dr. CHRISTISON remarks that the smallest fatal dose of sulphuric acid which he has found recorded, was one drachm, which was taken with sugar by mistake for stomachic drops by a stout young man, and produced death in seven days. A man has recovered after taking six drachms. In a case of poisoning with hydrochloric acid, an ounce and a half proved fatal in about twenty-four hours; and in another case, alluded to by TAYLOR, a man walked about three quarters of a mile after taking nearly an ounce. Mr. ORR and Dr. CRAIGIE refer to two cases of recovery, although two ounces of the concentrated sulphuric acid had been swallowed in each.

143. *k. The symptoms of the second of these varieties*, according to TARTRA, are at first those already described, but they soon abate in violence. The patient then becomes affected with general fever, dry skin, difficult breathing, tension of the abdomen, spasms, and pains of the limbs, salivation, and occasional vomiting, particularly of food and drink. The salivation is attended by fetor, and membranous flakes, resembling the villous coat of the stomach, are vomited. These flakes are most probably membranous exudations of lymph, resembling those of croup, thrown out on the excoriated and inflamed surface of the organ. Worms are sometimes discharged dead and exoriated by the acid. The functions of digestion and assimilation are arrested, or remarkably impaired, and the frame becomes extremely debilitated and emaciated. Death usually takes place in periods varying from a fortnight to several months. TARTRA adduces an instance in which death did not take place until after eight months, the vomiting of membranous flakes continuing until the last.

144. *l. The third and fourth varieties* described by M. TARTRA are characterized, as respects the former of these, chiefly by the greater mildness of the symptoms from the commencement, and

by the patient continuing through life liable to attacks of pain in the stomach, vomiting of food, and general disorder of the digestive functions. The latter consists of cases of perfect recovery. Of 55 cases of poisoning by the mineral acids recorded by TARTRA, 26 died; 19 of the primary, and 7 of the secondary effects. Twenty-nine recovered, and of these 21 perfectly. Suicidal cases, for obvious reasons, were more frequently fatal than the accidental.

145. *m.* The strong mineral acids, as above mentioned (§ 137, 138), may not reach the stomach, especially when the poisoning is accidental or attempted criminally. The effects produced by them, under these circumstances, upon the pharynx, œsophagus, and larynx, being often so violent as to occasion death in a few days. Several instances of this kind have been recorded; and even when a person has discovered his mistake, and taken only a small portion, which could have reached no farther than the pharynx or upper part of the gullet, partial recovery may take place, with stricture of the upper portion of the œsophagus; or fatal inflammation of the pharynx and larynx, with or without asphyxia, may be the immediate result. That a large proportion of the children poisoned, by the abandoned classes, with the mineral acids, die from the effects of the poison on these parts, without reaching the stomach, is proved in some cases by the appearances observed after death, and is rendered probable in others by the circumstances under which the act is perpetrated. In the case recorded by Mr. ARNOTT, the injury was confined chiefly to the larynx and gullet, the stomach being distended with food and very little affected. The symptoms were general depression, with croupy respiration and threatened suffocation, for which tracheotomy was performed, with relief to the breathing; but the patient died, with symptoms of general exhaustion, in thirty-six hours, without presenting any marked signs of the operation of the acid on the stomach.

146. In the circumstances and in the concentrated form, in which the stronger mineral acids are poisonous, whether taken accidentally, or with a suicidal intention, or given with a criminal object, danger or death arises chiefly from the local or structural change; comparatively little of the acid, as stated above (§ 134), being carried into the circulation. But these acids may be taken in such states of dilution as will admit of their absorption, and action on the frame through the medium of the blood; and thus they may produce noxious effects, especially when given frequently, or in too large quantity, or a form of *slow poisoning*; but as they do not act by producing a corrosive effect, when given in states of dilution which admit of their absorption, they will be considered, in this form of exhibition, under the class to which the different effects they then produce more appropriately belong.\*

147. *n.* *Appearances after death from the concentrated mineral acids* may be confined chiefly to the fauces, pharynx, larynx, and œsophagus, and may be comparatively slight in the stomach. The whole of the alimentary canal, from the mouth to the anus, should be examined, and the lesions of the upper portions should be

carefully observed; as these portions, especially those particularized, suffer most in cases of poisoning with these substances. Spots on the skin, about the mouth and lips, are often present, and should be examined. If the case have proved fatal within the usual period, and if the concentrated sulphuric acid have been swallowed, the inner surface of the mouth is generally white, softened, and corroded, the mucous coat is readily detached, and the tissues underneath are of a dark red. The same change is observed in the fauces, pharynx, and œsophagus, the colour of the mucous surface of these parts sometimes being brownish or ash-gray. The mucous membrane is often more or less corroded, partially detached, and, in the œsophagus, assumes longitudinal plicæ, owing to the contraction of the canal and its partial detachment. The stomach is usually contracted, corroded, and sometimes perforated. When opened, its contents are commonly of a dark brown or black hue, of a tarry consistence, and consisting chiefly of altered blood and mucus. The existence of acidity depends upon the treatment and the period which had elapsed from the ingestion of the acid. The villous surface of the stomach is traversed by black striæ, is more or less corrugated, or is generally of a brownish or black colour, which is not removed by washing. Between the rugæ and underneath the blackened membrane, the issues are of a deep or dark red hue; but this redness and the blackness of the villous membrane are sometimes partial, or in patches of various extent. The small intestines, especially when much of the acid has passed into the stomach, are more or less inflamed, their contents much resembling those of that viscus. When perforation of the stomach has taken place, all the coats are much softened, especially in the vicinity of the perforation, the margins of which are black, irregular, and very soft. The contents of the viscus may not have escaped through the aperture; but if they have passed through, the adjoining organs are generally altered by the acid. Mr TAYLOR refers to a case in which the spleen, the liver, and the coats of the aorta were found corroded and blackened by the acid which had escaped through the perforation.

148. When the acid has been taken in a diluted state, or at least in a less concentrated form, and if the patient live some days or weeks, the œsophagus is more or less constricted, and its mucous surface inflamed or otherwise changed. Inflammatory lesions are commonly found in the stomach, and the corrosion or charring of the villous membrane is not so great as described above. The blood in the vessels is always very dark; that in the vessels of the stomach and spleen is almost black and coagulated. In the more prolonged cases the villous coat of both the œsophagus and stomach is either more or less abraded, ulcerated, or almost entirely destroyed. The pylorus is generally constricted. In these cases the patient sinks from the irritability of the stomach, from the almost total arrest of the functions of digestion and assimilation, and from the action of the acid upon the blood and nervous systems. In some, at least, of these cases, and especially when the acid has been much diluted, a partial absorption of it into the circulation takes place, and changes the colour

\* In these cases they may readily be detected in the urine.—*Lond. Med. Gazette*, May 27, 1842.]

and state of the blood, and acts otherwise injuriously on the frame, as will be noticed more fully in the sequel.\*

149. *o. The appearances produced by the nitric and nitrous acids* are not materially different from those caused by sulphuric acid. The external surface of the lips often present yellowish or yellowish brown spots, the cuticle being easily detached. Yellowish spots are sometimes found about the neck, or on the hands. A yellow frothy liquid escapes from the mouth and nose. The abdomen is often distended with flatus. The inner surface of the mouth and cheeks is of a whitish or yellowish colour. The pharynx, larynx, and œsophagus are softened, tumefied, of a yellowish or brown colour, and their mucous membrane is easily detached, or it is already detached in long shreds or folds. The stomach is similarly altered. It is rarely perforated, and is often distended with gas. The villous membrane presents extensive patches of a yellowish, brown, green, or black hue, and the coats of this viscus are remarkably softened throughout. The duodenum is often changed in a similar manner, although not so extensively; the other intestines are seldom much altered. The non-perforation of the stomach is most probably owing, as Mr. TAYLOR suggests, to the circumstance of the acid having been swallowed, in most instances, while the stomach contained much alimentary matters. When death takes place rapidly, the contents of this viscus generally yield more or less of the acid. When the larynx is implicated by swallowing this or any of the other strong mineral acids, more especially if suffocation have been thus produced, the lungs and mucous membrane of the trachea and bronchi are congested with black blood. In more chronic cases, especially if the patient has lived several weeks, softening, redness, and ulceration in various stages of the mucous membrane of the œsophagus and stomach are found. The œsophagus is often constricted, and constriction is sometimes, also, met with in the pylorus and duodenum.

150. *p. The hydrochloric acid* produces similar symptoms and appearances after death to those which have been now described. Cases of poisoning by this acid are much more rare than by the other strong mineral acids; but those which have been observed with due attention present the same phenomena and lesions as are produced by nitric acid.

151. *q. Instances of poisoning by an admixture of mineral acids*—by the *nitric and muriatic acids*—*aqua regia*, which is often used in the arts for dissolving gold and platina—and by the *nitric and sulphuric acids*—*aqua regina*, which is employed for dissolving silver, may occur, but they have been very rarely met with. ORFILA

\* The following case is reported by Dr. TOOTHAKER, in the Boston Med. and Surg. Journal, vol. xv., p. 270. An ounce of the official muriatic acid was swallowed by mistake, and immediately succeeded by violent burning of the mouth and fauces, a sense of suffocation, and spasms. Olive oil was given, followed by milk and water, thickened with calcined magnesia. Copious vomiting succeeded. An emetic was next administered, and this again followed by magnesia. The strength was greatly reduced, and the extremities so cold as to require the application of sinapisms. The next day there was pain and costiveness, but these were relieved by a dose of castor oil. After this, the patient gradually recovered, although not without subsequent symptoms consequent upon the action of the corrosive substance which he had taken.]

has given one instance of poisoning by the latter of these combinations. The symptoms and post-mortem appearances were much the same as those already stated, but approached the nearest to those caused by the nitric acid, which predominated in the mixture. The *nitro-muriatic acids* most probably produce symptoms and changes very closely resembling those described above, especially those in connexion with nitric acid (§ 139–149);\* but they have not hitherto been recorded.

152. *r. Treatment.*—The difficulty of swallowing, in almost every instance of poisoning by these acids, is the great obstacle to the treatment of their effects. The means and the intentions which should guide the employment of them are obvious; but when the constriction of the pharynx and the spasmodic action of the pharyngeal muscles are such that all articles are forcibly rejected upon every attempt to swallow them, the most influential antidotes and remedies are altogether prevented from exerting their effects. If, however, the patient be still able to swallow, calcined magnesia, or the carbonate of magnesia, should be instantly given in milk, or in any mucilaginous fluid; but if these are not immediately to be procured, finely-powdered chalk, whiting, common soap or soda should be substituted, and taken in milk, or in water, or in oleaginous or mucilaginous fluids, according as either may be in instant readiness. The success of treatment entirely depends upon the rapidity with which the *antidote* is administered. Oleaginous and mucilaginous fluids should be freely administered. Linseed or olive oil, linseed tea, gruel, milk, [flour and water], are severally of use when they can be swallowed, either alone or as the vehicles of the antidotes just named.

153. If swallowing be impossible, owing both to the constriction and to the tumefaction and irritability of the pharynx and œsophagus, the propriety of introducing the remedies now mentioned by the tube of the stomach-pump into the stomach should be considered. The tumefaction of the coats of these passages, the corrosion and softening they have experienced, and their partial detachment, and the frequent recurrence of severe singultus, are often such as almost to preclude the introduction of the tube, and to risk perforation of the canal in the attempt. ORFILA, in 1817, recommended a recourse to the stomach-pump, which, however, was first proposed by BOERHAAVE, and strongly advised by RENAULT and DUPUYTREN shortly before the recommendation of ORFILA. But, although thus approved of, this apparatus appears never to have been brought into use until

\* The plan of my work and my limits prevent me from entering upon the *chemical analysis and tests* of the several poisons. If these several topics cannot be fully discussed with reference to the states, combinations, &c., in which poisons should be investigated by the medical jurist, and to the various objections which may be urged against certain methods of analysis and tests, in ever varying circumstances, they should be entirely relinquished; and it is preferable that the reader should consult either of the able productions of BECK, CHRISTISON, ORFILA, DEVERGIE, TAYLOR, and GUY, as to these matters, than that I should give an insufficient account of them; and to such an account my limits must necessarily have confined me.

[The American reader will have little cause to regret the omission of this part of toxicology, inasmuch as the works of TAYLOR, BECK, and GUY are in almost every medical library. The editor would particularly recommend the recent work of TAYLOR on Poisons, as containing everything needed or known on this important branch of medicine.]

1822, when its utility was demonstrated by the practitioners mentioned above (§ 100.) It is obvious that the prospect of having recourse to it with advantage, in the circumstances now under consideration, must depend upon the peculiarities of the case, and the acumen and dexterity of the surgeon.

154. When the larynx is affected, causing difficulty of breathing approaching to suffocation, *tracheotomy* should be performed; nor should this operation be then delayed, as prolonged difficulty of breathing causes more or less congestion of the lungs and bronchial membrane, which always accelerates a fatal issue, which issue the lesions of the stomach and œsophagus might not otherwise have produced.

155. Having neutralized the acid, our chief endeavours should be next directed to the removal of the effects which may be inferred to have been produced by it. Mucilaginous fluids, almond or spermaceti emulsions, gruel, decoction of marsh-mallows, gum-water, sugared water, thin broths, especially veal broths and jellies, may be severally given, and warm baths may be allowed. If the patient complain of colicky pains, of dysuria, or of tenesmus, starch, or other demulcent and oleaginous enemata, especially those with olive oil, with gruel or with veal or mutton broths, &c., should be administered from time to time; for, under any circumstance of the case, these enemata will be of service.

156. The symptoms of *pharyngitis*, or of *œsophagitis*, or of *gastritis*, or of the association of these affections, which frequently continue until either a fatal issue or recovery results, should be treated conformably with the principles advised for these maladies. But generally the amount of vascular depletions required for the idiopathic sthenic inflammations of the alimentary canal is not required after poisoning by these strong acids. The frame has received both a severe injury of its violent organs and a violent shock; and the former generally prevents the reaction usually consequent upon the latter. Hence venesection may not be required, or it may even be dangerous: the habit of body, strength, age, and circumstances of the case, in connexion with the degree and character of existing vascular action, being the guides to the adoption either of this practice or of moderate local depletions, or merely of emollients, of demulcent broths, of mucilaginous diluents, of gelatinous and farinaceous articles, and of external derivatives.

157. The irritability of the stomach, and the spasms and pains of the voluntary muscles and extremities which often continue for several days, both in cases which recover and in those which end fatally—these pains and spasms being caused by the injury and irritation sustained by the visceral or ganglionic nerves, the morbid conditions of these nerves being extended to the sensory nerves, and reflected upon the voluntary muscles by the motory nerves—are among the most distressing symptoms which are afterward experienced, and are alleviated with the greatest difficulty. In these circumstances, emollient and tonic substances may be given in small and frequent doses, with opium or the tinctura camphoræ composita; or the simple infusion of roses may be prescribed, with tinctura opii; or the compound

tragacanth powder, with the pulvis eretæ compositus cum opio, &c.; and warm terebinthinate epithems or embrocations should be repeatedly applied to the abdomen. Nourishment of a mucilaginous, gelatinous, or demulcent kind should be taken in small quantity and at short intervals; and if deglutition continue difficult, strong broths and animal decoctions ought to be administered *per anum*. For this latter important and sometimes fatal affection, the emollient linctures and other means recommended for *acute and chronic inflammations and stricture of the œsophagus* (art. OESOPHAGUS, § 43, *et seq.*), may be appropriately have recourse to. (See, also, STOMACH, *Diseases of*.)

[We have treated three cases of poisoning by sulphuric acid, two of which died and one recovered. The poison was drank from a vial, by accident in every case, and the quantity swallowed from one to three drachms. The symptoms were those detailed above. Death occurred in one case from the inflammation extending down the trachea, causing all the symptoms of croup, and causing death by suffocation, about the 5th of August. In the other fatal case, death occurred on the third day, from acute gastritis. In the case of recovery, alkalies, as whiting, with abundance of mucilage, were freely and early administered.]

158. *s. Sulphate of Indigo.*—Poisoning by this substance is chiefly accidental. Mr. TAYLOR has observed that, as this compound is nothing more than a solution of indigo in sulphuric acid, the symptoms and post-mortem appearances caused by it are the same as those which have been described as produced by the latter substance. Poisoning by it may be suspected when, with these symptoms, the internal surface of the mouth has a blue colour, the vomited matters also having a deep blue tint. In two instances, in which about an ounce each was swallowed, death took place: in one case, eleven hours afterward, and in the other in seven hours and a half. It was remarked that the urine which was passed had a bluish tinge, indicating the absorption of some portion of this compound into the circulation. The treatment of poisoning by the sulphate of indigo is not different from that directed for the effects of the mineral acids.

159. *C. OXALIC ACID.*—Poisoning by this acid is generally accidental or suicidal. Of nineteen cases of poisoning by this substance in the coroners' return for 1837 and 1838, fourteen were suicidal. Owing to the resemblance of this acid to Epsom salts, it has sometimes been taken for them. Mr. TAYLOR thinks that its intensely acid taste prevents it from being often used with criminal intentions, although he has known several instances of murder having been attempted by it.

160. *a. The symptoms* are immediate, and so intense as often to have destroyed life before the arrival of the practitioner. If the poison be taken in large quantity—from half an ounce to an ounce dissolved in water—a burning acid sensation is felt in the fauces, throat, and œsophagus, followed immediately by vomiting. In some instances the impression of the acid on the stomach has been so intense as to paralyze this viscus, and the parts associated with it in the act, and little or no vomiting has occurred, death, however, rapidly taking place;

in other cases, the vomiting has been incessant until death. The vomited matters are intensely acid, and have a green, or nearly black, colour, consisting of the alimentary substances, and afterward chiefly of altered mucus and blood. Extreme anxiety, pain, and tenderness are felt at the epigastrium; and often, in both, hypochondria, followed by spasms, singultus, convulsions, collapse of the features, and of all the vital actions, by clammy perspirations and cold extremities. Attending these there are often, also, stupor, unconsciousness, a small, irregular, and almost imperceptible pulse, deep and slow respiration, numbness of the limbs, and death.

161. In smaller quantity, and in somewhat greater dilution, the sensation of acidity, of burning in the throat, and the vomiting varies accordingly. Should the patient survive some time, owing either to the quantity of the poison taken, to the presence of food in the stomach, or to the discharge of the greater portion of the acid by vomiting, soreness and constriction of the throat, painful and difficult deglutition, irritability of the stomach, thirst, tenderness at the epigastrium, hiccough, diarrhoea, flatulence, and great depression of the vital powers are the most constant symptoms. Soreness of the mouth, swelling of the tongue, and numbness and tingling of the limbs, are often also experienced; the patient either dying after two, three, or several days, or slowly and altogether recovering. But recovery is generally attended and followed by more or less disorder, or tendency to disorder, of the digestive organs.

162. *b. The quantity of oxalic acid* which may destroy a human life has not been determined. The immediate rejection or the retention of the poison by the stomach, and the promptness or absence of medical aid, necessarily determine the result. Mr. SEMPLE recorded a case in which two drachms, dissolved in water, were swallowed. Vomiting took place immediately, and the symptoms had nearly disappeared in about twelve hours. A man swallowed three drachms; vomiting instantly occurred, and he recovered in a few hours. A girl is stated by Dr. BABINGTON, of Coleraine, to have taken forty grains: severe symptoms of gastric irritation supervened; but although, as in the other cases, medical aid was procured, the recovery was protracted. Mr. TAYLOR states, that a smaller dose than half an ounce generally has not been fatal; although it may be inferred, from the very dangerous effects caused by much smaller quantities, that much less than this may destroy life, if judicious treatment be not resorted to. When the dose of this poison is upward of half an ounce, death is commonly the result; but instances of recovery have occurred where the quantity was much greater than this, and judicious treatment has been promptly administered.

163. *c. The period at which death may take place* varies with the circumstances already alluded to. Dr. CHRISTISON mentions a case where an ounce of this poison killed a girl in thirty minutes, and another where the same quantity was fatal in ten minutes, this being the shortest period on record. When the dose is half an ounce, or upward, death commonly takes place within an hour or two. But in

stances have occurred in which life has been prolonged for thirteen or fourteen hours. Mr. FRAZER has recorded a case which was prolonged to twenty-three days; irritability of stomach, singultus, fever, and exhaustion being the prominent symptoms.

164. *d. Appearances after Death.*—The mucous membrane of the mouth, fauces, and œsophagus is usually white; but it is sometimes partially covered by the dark matters discharged by the stomach. This membrane may be readily detached in these situations, as well as in the stomach. This organ is commonly much softened and pulpy, and contains a dark-brown, acid liquid resembling coffee-grounds, from the admixture of altered blood with it. Blood-vessels are seen ramified distended by coagulated, black blood. In a case where nearly two ounces were taken, and death was rapid, the coats of the stomach presented nearly as carbonized an appearance as that occasioned by sulphuric acid. The œsophagus presents similar changes. It is generally pale, seems as if boiled in water, and its inner membrane is raised in longitudinal rugæ or folds, interrupted by patches of abrasion. The upper portions of the intestines, especially the duodenum, are sometimes slightly inflamed or softened, but they are not otherwise remarkably altered. In Mr. FRAZER's case, in which life was prolonged twenty-three days, the villous coat of the stomach and gullet was either softened or entirely detached. The muscular coat was exposed in several places, and was thickened, softened, injected, and inflamed. This acid has not so corrosive an action on the coats of the stomach as the strong mineral acids, as it rarely entirely perforates these coats, although it softens them and destroys their physical as well as vital cohesion. In some instances the inner surface of the trachea has been found inflamed, owing to its anatomical connexion with the œsophagus. In a few cases the lesions have been very slight, although the symptoms were severe; but little beyond softening of the coats of the stomach having been remarked.

165. *e. Death is the result* of the corrosive action of this acid upon the organization of the upper portions of the digestive canal, especially of the stomach, the nerves of the organ being more particularly affected. But the operation of this poison is thus limited only when large doses of it are taken, and then the local injury and disorganization and consequent vital shock are sufficient to destroy life. It has not been found to affect the larynx so as to threaten suffocation. When swallowed in smaller quantity, or in states of dilution, it is manifestly absorbed, and acts upon the nervous system and on the blood (§ 25, *et seq.*). Much of the change observed, both in the tissues of the stomach and in the blood, in cases of rapid poisoning by this substance, has arisen from the action of such portions of it as have still remained in, or been imbibed by the stomach at the time of death, the changes found on inspection having been partly thus produced *post-mortem*.

[Dr. C. T. JACKSON has reported an interesting case of poisoning by oxalic acid, in the thirtieth volume of the Boston Med. and Surgical Journal, p. 17. A man, aged 30, took, February 1st, at half past eight A.M., about one third of a

tea-cupful, or about one ounce, of the crystallized oxalic acid, mistaking it for Epsom salts. He immediately perceived, by the strong acid taste, burning sensation in the throat, &c., that he had made a mistake, and he immediately drank a large quantity of warm water to excite vomiting, which produced the desired effect. He also took ipecacuanha by the advice of a physician. This was followed by antimony in emetic doses, and castor oil. When called at half past eight P.M., Dr. J. found him in a state of complete prostration; face, lips, throat, and tongue swollen and livid; pulse almost extinct, fluttering, and irregular; heart, in a continual fluttering palpitation; great jactitation and distress, with incessant vomiting. The matter evacuated by vomiting was a thick, grumous, and jelly-like fluid, of a yellow colour, mixed with white flocculi. He complained of no pain at the epigastrium, or over the bowels, on pressure, but the distress and anxiety were very great. The matter first brought up by vomiting was of a dark chocolate colour. Dr. J. ordered carb. lime,  $\text{zij}$ , mixed with camphor and opium, five grains: this was given in divided doses, but rejected; an enema of soap and water was also given. February 2d, face tumid, and of a livid colour; tongue swollen and livid, pulse 130; urine entirely suppressed; gave an infusion of salts and senna; vomiting continued for two or three days, with great distress and anxiety; tongue became covered with a brown coat, with a red, dry tip; great thirst, no pain. The case was treated like one of gastritis, with general and local bleeding, morphia, &c. On the 6th, his mind began to wander, and petechiæ appeared on the face, head, chest, nates, &c., appearing as if sprinkled with blood. He continued to fail, and died on the 10th, ten days after taking the poison.

*Post-mortem Examination.*—Muscles rigidly contracted; numerous petechiæ; emphysema of lower lobe of left lung; unusual infiltration of serum in lungs; left side of heart empty of blood; the right contained a small quantity; gall-bladder distended with yellow bile; stomach contained a yellow fluid, evidently coloured with bile; stomach remarkably corrugated; mucous membrane very bright red, especially in small curvature of the organ and around the cardiac orifice; numerous small ulcers in the mucous membrane, which was much thickened and soft; the mucous surface of the duodenum was red, and also thickened, and studded with ulcers; also that of the jejunum and ilium congested; Peyer's glands not enlarged; small intestines contained soft, yellow, fluid fecal matter; the large intestines contained scybala of fecal matter; mucous membrane healthy; spleen natural; bladder contained some urine.]

166. *f. Treatment.*—The antidotes against this poison should be most promptly resorted to. The best are chalk, calcined magnesia, or the carbonate of magnesia. These should be abundantly mixed in water, or milk, or in any oleaginous or demulcent fluid instantly at hand. Lime-water and oil may also be given. As chalk is the best antidote, Dr. CHRISTISON advises that even the plaster of the apartment should be broken down in order to be given; but it would be difficult to reduce the plaster in a very short time to a powder sufficiently fine to admit of admixture, and of deglutition

in the existing state of the patient. Free dilution—copious draughts of demulcents, emollient decoctions, &c., are generally of use; but they should be given in large quantities, and their rejection, by irritating the fauces, should be encouraged. If dilution be not free and frequent, it may be injurious, by dissolving the poison and by favouring its absorption. If vomiting can be produced after the antidotes and much fluid have been taken, it should be encouraged by means of oleaginous and emollient fluids; but recourse to the stomach-pump is of doubtful efficacy, as it may injure, or even perforate the softened coats of the œsophagus and stomach. When it can be easily introduced, and when there is little or no singultus, antidotes and demulcent fluids having been already freely swallowed, then it may be of use, if vomiting does not take place, for the removal of the contents of the stomach, and for the introduction of remedial agents when deglutition cannot be accomplished. But it should not be overlooked that the pharynx and gullet have sustained nearly as great an injury as the stomach, and that the too early use of this apparatus will prevent the antidotes and other medicinal substances which should be swallowed from exerting a salutary effect upon those parts. As the salts which the alkalies form with oxalic acid are as injurious as this acid itself, neither the alkalies nor their carbonates should be given after poisoning with it. The consecutive effects of this substance should be treated as those of other corrosive poisons, or as the operation of this acid requires when given in small or diluted doses, and when acting as will hereafter be shown. (See next CLASS.)

167. ii. ALKALIES.—*Ammonia, potash, soda, and their carbonates—pearlash, soap-lees.*—*a.* The vapour of strong ammonia may rapidly destroy life, when inhaled, by producing acute inflammation of the larynx and trachea, often extending to the bronchi and lungs, and all the symptoms of violent croup. When ammonia is held too near the nostrils to rouse persons from syncope, its vapour may act more or less as an irritant of the respiratory mucous surfaces, and be injurious not only in this way, but also in as far as it prevents a due supply of air to the lungs.

168. *b. The symptoms occasioned by the fixed alkalies*, when taken in large quantities, are nearly the same as respects the caustic states of these alkalies; the subcarbonates and carbonates being more mild in their operation. Poisoning by these substances is generally caused by accident. When the caustic alkalies are swallowed, an acrid, corroding taste and pain, with a sensation of burning and excoriation, are felt in the mouth and throat; these latter sensations proceeding along the œsophagus to the stomach and epigastrium. Vomiting often occurs, and the matters thrown off usually consist of soft substances, resembling the softened, detached portions of the villous tissue, with mucus, often mixed with dark, discoloured blood, and with alimentary articles more or less altered, in the first instance. Both these and other associated symptoms vary with the concentration and quantity of the alkali; but vital depression soon appears. The mouth, tongue, and throat present a tumefied, soft, flabby, and inflamed appearance; the surface becomes cold and clammy; the pulse feeble,

small, and quick; singultus is often present; the pain extends to the central and lower regions of the abdomen, and diarrhœa supervenes and becomes urgent and exhausting. The symptoms are somewhat less severe when the carbonates have been taken, unless the dose of these has been very large and the solution very strong.

169. *c.* *Ammonia* and its sesquicarbonate produces nearly the same symptoms as the fixed alkalies; the chief differences being, that strong solutions of the former occasion a more violent burning pain in the fauces, œsophagus, and stomach than the latter, the larynx being oftener implicated. But poisoning by ammonia is not common, cases of it occurring chiefly by mistake, which is most frequently discovered before much of it is swallowed; and then the fauces, pharynx, larynx, and œsophagus are severally more or less affected, according to the strength of the solution. Ammonia is not so productive of vomiting as the fixed alkalies, when taken in poisonous doses, the symptoms being more closely allied to those of gastritis, associated with enteritis and œsophagitis; and it seldom occasions diarrhœa. In the more concentrated states ammonia also occasions singultus and convulsions.

170. *d.* The quantity required of these substances to produce death necessarily varies with the concentration of the solution, and with the state of the stomach as respects the quantity of aliments in it, and other circumstances. The caustic alkalies are fatal in smaller quantity and in less time than the carbonates and the preparations of ammonia. ORFILA adduces two instances in which half an ounce of the carbonate of potash was fatal, the patients having lingered for several months. The exact quantity, however, cannot be assigned; for a comparatively small one, if the alkali be caustic, or if it implicate the larynx, may be rapidly fatal.

171. *e.* The duration of the symptoms, or period which usually elapses until death occurs, may be very short, especially as respects the caustic alkalies. Mr. TAYLOR estimates the shortest period at three hours; and in this case death was caused by three ounces of a strong solution of the carbonate of potash. When the substance attacks the larynx, as often occurs in respect of the mineral acids, this period will also be short. The more immediate effects of the caustic alkalies usually terminate fatally in two or three days; the softening and disorganization of the villous surface of the digestive canal, and the arrest of circulation in the vessels supplying this canal, terminating life in a very few days, and even in a shorter time, if the extent of injury be such as to occasion severe vital shocks in addition. When the injury is less, or the vital resistance to it greater, the patient may linger for weeks, or even months; the solution, abrasion, or excoriation of the villous surface of the stomach, and of other parts of the canal, being attended by pain and tenderness in the hypochondria and other regions of the abdomen, with vomitings, anorexia, indigestion, diarrhœa, and often, also, with difficult or nearly impossible deglutition. Owing to the injury or destruction of the digestive villous surface, digestion and assimilation are impaired or arrested, and the patient sinks from

the inanition thus occasioned by the local injury; whatever amount of absorption of the poison may have taken place into the circulation, in cases where the substance has been more diluted, and the local injury less, acting a very subordinate part in producing the ultimate result.

172. *f.* The appearances after death consist chiefly of a diffiuent softening, abrasion, or detachment of large portions of the villous surface of the fauces, pharynx, œsophagus, and stomach; and sometimes also of parts of the duodenum and intestines. The internal surface of the canal, especially of the stomach, presents a chocolate colour; and the contents are fluid, viscid, and often dark from the admixture of exuded blood. The softening of the coats of the stomach sometimes extends to all the coats, but especially to the more internal; and much resembles the gelatinous softening met with in the stomach in rare instances, and attributed to the action of the gastric juices after death (see § 84-87); but there have been more tumefaction and darker discoloration in the poisoning now being considered. When death has been produced by ammonia or its sesquicarbonate, the softening and tumefaction have been attended by signs of inflammation and excoriation, inflammatory appearances existing also in the trachea and larynx.

173. *g.* Of the action of the alkalies and their carbonates it may be concluded that, in their concentrated states, in large quantities they are fatal chiefly by their local action, in the way stated above (§ 171, 172); and that, in weaker forms or in small doses, they are more or less absorbed, as demonstrated by the composition of the urine and other secretions but they are generally eliminated by the mucous excretories before they accumulate in the blood to a very injurious amount.\*

174. *h.* The treatment of the alkaline poison consists in the immediate exhibition of fluid containing vinegar, or any of the vegetable acid which may be obtained with the least delay. If any of these be not quite at hand, draught of beer or of malt liquors; or demulcents with oil, or milk, gruel, &c., may be taken until these acids are procured. A tepid infusion of chamomile flowers is afterward of use in promoting vomiting, and it may be given with or without moderate doses of the sulphate of zinc. The stomach-pump may be more injurious than beneficial, especially if the caustic fixed alkalies have been taken, for the tumefaction and softening of the coats of the œsophagus and stomach are often so great as to render it difficult to introduce the tube without causing laceration or injury.

The treatment of the secondary effects of these poisons consists chiefly in removing the effects which may be inferred from the symptoms still to continue. At first demulcents, oleaginous and emollient substances, may be administered, and afterward gelatinous and far-

\* When injected into the veins, ORFILA believed that the alkalies caused death by coagulating the blood. I find it remarked in my note-book, when detailing some experiments with the alkalies, in which I was concerned in 1820, that "the alkalies and their carbonates, when injected into the veins, appear to destroy life by impairing organic nervous energy, the irritability of the heart, and the functions of the brain, and by their influence on the nervous masses and structures while circulating in the blood-vessels and capillaries."

inaceous articles of food in small quantities may be given. An attempt may be made, with caution, to restore the tone of the villous surface, by giving small doses of *creasote* with demulcents, or of the pyroligneous acetic acid, or the compound infusion of roses with small doses of quinine, or of the sulphate of zinc, or such of the tonic and astringent infusions or decoctions as may be found to agree the best with the stomach. When the difficulty of swallowing and continued irritability of the stomach excite fears of abrasions of the villous coat of the digestive canal, and if diarrhœa warrant the supposition that this lesion extends as low as portions of the intestinal tube, then astringents and tonics, vegetable or mineral, as either appears most appropriate, should be given in small but frequent doses, with small quantities of opium, in demulcent and emollient vehicles. By attempting to support vital power by suitable means, and to restore the tone of those parts of the villous surface which have been the least injured, nature will thereby be the better able to reproduce in some measure the abraded portions, or in some way to supply their functions. In other respects the treatment, the diet, and the regimen should be adapted to the features of particular cases, with a careful observation of the *juvantia* and *lædencia*.

175. iii. ANTIMONY—CHLORIDE OF.—*Butler of Antimony*.—This is the only preparation of antimony which I shall notice as a *corrosive poison*; the other preparations of this metal being more or less absorbed, and acting otherwise on the system. The *chloride*, as usually employed, is a very corrosive liquid, varying in colour, according to the quantity of iron it contains, from a light yellow to a dark red. Poisoning rarely occurs from it. Mr. TAYLOR, however, refers to three cases which have been recently recorded: two were caused by mistake, one intentionally; and in this last between two and three ounces of this solution were swallowed.

176. a. The *Symptoms* were in many respects the same as those described above as being caused by the caustic alkalies: a burning pain in the throat, course of the œsophagus, and stomach; constant efforts to vomit; collapse of the features, coldness of the surface and extremities, and faintness; a small, weak, and frequent pulse; pains in the abdomen, with tenesmus, but no evacuations. To these succeeded drowsiness, convulsions, and, in the suicidal case, death in ten and a half hours. The two accidental cases recovered, much smaller quantities of the poison having been taken.

177. b. *On inspection after death*, the fatal case presented the internal surface of the digestive canal, from the mouth to the jejunum, of a black and charred appearance. The mucous membrane was destroyed throughout this extent: "there was none of this membrane, in general, remaining, only a flocculent substance, which could be easily scraped off with the back of the scalpel." The subjacent coats were so soft as to be torn with the greatest ease.

178. c. The *treatment* should consist chiefly of copious draughts of water, or emollients and demulcents containing sugar, and, after free vomiting has been procured, with opium or sirup of poppies. If vomiting does not imme-

diately follow the ingestion of this poison, ORFILA recommends that a decoction of cinchona, or of willow or oak bark, or of powdered gall-nuts, should be freely taken as soon as possible. The treatment of this poison does not differ from that advised for the fixed alkalies as respects either these substances or those mentioned under that head. See, also, the *preparations of antimony* in CLASS V.—ACRO-SEDATIVE POISONS.

179. iv. IODINE AND BROMINE.—A. a. *Iodine* acts differently on the economy, according to the concentration of the tincture or solution of it which may be used. In a state of strong spirituous or ethereal solution it acts as a powerful corrosive of the tissues to which it may be applied; but in weaker solutions, and in various states of combination, it is much less corrosive, or is merely an irritant, and is more or less copiously absorbed into the circulation. In these states it acts as an irritant and alterative, or *acro-alterative poison*, in which class I have considered it and its preparations.

180. b. The *fumes of iodine*, when inhaled, produce a violently irritating effect upon the respiratory passages, especially the larynx and trachea. If the vapour is concentrated, it occasions constrictive irritation and inflammation of these parts, which may be followed by asphyxia. In milder states it occasions inflammation of the air-passages, with or without pneumonia. I have seen more than one case in which the vapour of iodine had been resorted to in the treatment of pulmonary consumption, with the effect of producing dangerous bronchitis, owing to the strength of the vapour which had been inhaled.

181. c. *Applied externally*, iodine, in a concentrated or pure state, or in that of a strong tincture, acts as a caustic, and changes the cuticle to an orange-yellow colour, causing desquamation, and, if allowed to remain, inflammation and destruction of the tissue with which it comes in contact. In weaker states of solution it acts as a desiccant of secreting or mucous surfaces, and inflames them more or less intensely. Hence, if injected, even in these states, into mucous canals, or taken into the stomach, it would act as an acrid corrosive poison.

182. d. *When iodine is swallowed* in a more or less pure or concentrated form, it produces the most violent sufferings, especially if the quantity be large; but the effects vary remarkably with the state and contents of the stomach at the time of its ingestion; for if this viscus contain much bread, potatoes, or farinaceous or amylaceous articles of food, the iodine will be thereby rendered much milder in action by forming an iodide of starch, as Dr. PEREIRA has remarked. Spirituous solutions of iodine, or the iodured solutions of the iodide of potassium, when swallowed in more or less strong or concentrated forms, cause a most acrid sensation, with constriction, burning pain, and dryness of the throat, descending down the œsophagus to the stomach, where they produce lacerating pains and efforts to vomit, extreme thirst, tenderness of the epigastrium, with anxiety, tremours, loss of strength, palpitations, faintness, sinking of the pulse, suffusion of the eyes, and restlessness. Dr. JAHN mentions a case in which an over-dose occa-

sioned violent pain in the abdomen, vomiting, profuse bloody diarrhoea, coldness and blanching of the skin, rigours, rapid pulse, &c. In a case noticed by Dr. CHRISTISON, a drachm and a half of the iodureted solution of the iodide of potassium produced acute pain and burning in the pit of the stomach, nausea, followed by vomiting of yellowish matters, which had the taste of iodine; by restlessness, headache, giddiness, and pallor of the countenance; and by recovery after five days. In a fatal case recorded by ZINK (*Journ. Comp.*, t. xviii., p. 126), the symptoms were restlessness, burning heat and dryness felt from the throat along the course of the œsophagus to the stomach, unquenchable thirst, palpitations, and a frequent, unequal, and weak pulse, violent priapism, copious diarrhoea, parched tongue, tremours, and faintness. The patient was bled; the blood was cupped and buffed. He died after five weeks. In another case, in which the tincture of iodine caused slow poisoning and death, M. ZINK found the following lesions:

183. *c. Appearances after Death.*—The intestines were distended with gases; effusion had taken place into the peritoneum; and adhesions had formed between several of the viscera. The gullet was much reddened internally, and remarkably constricted. The stomach was distended, and was externally inflamed in patches, and in one place apparently excoriated. It was inflamed internally, and corroded to a great extent near to the pylorus; the peritoneum covering the corroded part was detached and perforated with numerous small holes. The intestines were reddened and inflamed in places with patches approaching to splacelation. The liver was enlarged, and of pale red or rose colour. The gall-bladder contained a large biliary calculus. The spleen seemed inflamed in some places. The pleura contained some serum.

184. *f.* The quantity of this poison required to destroy life depends upon the concentration of the solution employed, and the nature and quantity of the aliments in the stomach. When the iodine is pure or in large quantity, in whatever state it may be employed, it acts as a corrosive or caustic poison, causing death by its local action. In states of weaker solution, or in combinations which weaken its action, or in small doses often repeated, it produces *slow poisoning*, as will be shown hereafter. It is then absorbed, and it accumulates in the system, producing emaciation and various morbid changes. The quantity required or the time taken to produce death has rarely been remarked in respect of this poison. Dr. GARDNER states that a scruple of pure iodine, in the form of tincture, destroyed a child four years of age in a few hours.

185. *g.* The treatment of the more corrosive states in which iodine may be given is not satisfactory. The stomach-pump should be early employed, and vomiting encouraged by giving fluids containing anylaceous and farinaceous substances. Starch enemata should also be thrown up, and demulcents taken frequently. [Irritation should be relieved by opiates.] In other respects the treatment should be the same as recommended for *gastritis*.

186. *B. BROMINE* is but little known as a poison. Its vapour is most irritating when

brought in contact with the conjunctiva.—*a.* When its vapour is *inhaled*, violent cough, a feeling of suffocation, with dryness and constriction of the larynx, are occasioned, and are soon followed either by inflammation of the respiratory passages, or by asphyxia. FRANZ had violent cough and sense of suffocation, followed by headache, instantly after momentarily breathing the vapour of bromine.

187. *b.* When a *watery solution is injected into the veins*, according to the experiments of FRANZ, BARTHEZ, DIEFFENBACH, and BUTZKE, it appears to coagulate the blood, and causes immediate death, preceded by convulsions.

188. *c.* Taken into the stomach, it is a more corrosive poison even than iodine. BUTZKE, after swallowing a drop and a half of this substance in half an ounce of water, felt heat in the mouth, œsophagus, and stomach, followed by colicky pains. Two drops occasioned nausea, hiccough, and increased secretion of mucus. (See CHRISTISON on Poisons, p. 1-5, and PEREIRA'S *Mat. Med.*, vol. i., p. 250.) From these experiments it is evident that bromine acts in a similar way to iodine in every respect; but that it is poisonous in smaller quantities than iodine, although the *symptoms* and changes produced by it in the digestive canal are the same as those occasioned by that substance. The treatment is the same for both poisons.

189. *v.* LIME acts as a corrosive poison when taken into the stomach, or applied to a vital part, in its caustic and unslacked state; but it is rarely so employed, even accidentally; two cases of this kind only being noticed by medico-legal writers. It is evident, from its caustic action, that the ingestion of it, or its introduction into mucous canals, will be followed by corrosion, and inflammation of the tissues with which it comes in contact. When employed in its quick state, it will even decompose or destroy the structures by imbibing their watery or fluid constituents.

190. *a.* When *swallowed*, it occasions heat, constriction, and pain in the throat, descending to the stomach, with unquenchable thirst, nausea, retchings, severe colicky pains, constipation, and the usual symptoms of corrosive poisoning, followed by nearly the same changes as have been already described, especially inflammation and corrosion of the parts with which it had come in contact.

191. *b.* The treatment should be the same, as respects *antidotes*, as that advised for poisoning by the fixed alkalies (§ 174), especially an immediate recourse to vinegar, lemon-juice, or any vegetable acid, and to demulcent drinks. Subsequently, if symptoms of gastritis, or gastro-enteritis are developed, vascular depletions, and the usual treatment of these diseases, should be prescribed.

192. *vi.* PHOSPHORUS, when minutely divided, proves a violent corrosive poison. According to the experiments of MAGENDIE and ORFILA, when it is dissolved in oil and *injected into the veins*, it occasions almost instantaneous inflammation of the bronchi and substance of the lungs.

193. *a.* It may be taken into the stomach either as an empirical remedy or accidentally; but its effects on man have not been often observed. It was at one time much employed, in small doses, in medical practice, especially as an aphrodisiac, and it probably occasioned dangerous

symptoms even when thus prescribed. It is generally *slow* in its operation, although it is poisonous in very small quantities, particularly when melted in warm water or in oil. The most rapidly fatal case I find noticed is that by Dr. FLACHSLAND. A young man took, at the recommendation of a quack, some of this substance on bread and butter, to cure general debility, constipation, and impotence. He was immediately seized with violent pain in the stomach, continual retchings, discharges after injections that shone in the dark; and he died in forty hours. The quantity of phosphorus taken was not known. Dr. CHRISTISON states, that a grain and a half proved fatal in a case which was mentioned by M. WORRE. A stout young man, having taken half a grain without injury, took a grain and a half in hot water. Seven hours afterward he was attacked with pain in the stomach and bowels, with incessant vomiting and diarrhoea, excessive tenderness and tension of the belly, and died exhausted in twelve days. M. JULIA-FONTENELLE relates the case of an apothecary who, after taking in one day first one grain of phosphorus, and then two grains, without experiencing any effects, swallowed next day three grains at once in sirup. In the evening he felt generally uneasy from a sense of pressure and constriction in the abdomen, which continued for three days, when he was seized with violent and continual vomiting of matters which had an alliaceous odour. On the seventh day, spasms, delirium, and palsy of the left hand supervened, and death speedily ensued. It is manifest that, if applied to wounds, or introduced into any of the natural canals, the effects would be very violent, and even fatal after a longer or shorter period.

194. *b.* The *morbid appearances* after poisoning with this substance have been recorded only in the cases observed by WORRE and FLACHSLAND (§ 193). In the case of the former, where only one grain and a half of this poison was taken, the skin was generally yellow, and livid in places. The lungs were gorged with blood. The muscular coat of the stomach was inflamed. The other coats near the two extremities of the organ were black. In Dr. FLACHSLAND's case, much fluid blood was discharged on making the first incisions. The omentum and external surfaces of the stomach and intestines were red. The villous coat of the stomach presented an appearance of gangrenous inflammation, which Dr. CHRISTISON suggests to have been black extravasation only; and the duodenum was similarly affected. The large intestines were contracted to the size of the little finger, and the mesenteric glands were enlarged. The kidneys and spleen were inflamed.

195. *c.* *Treatment.*—Large quantities of demulcent liquids should be exhibited, and magnesia given to neutralize any phosphorous and phosphoric acids which may be formed. Vomiting should be early encouraged by large mucilaginous draughts; and inflammation allayed by general and local depletions, or the latter only, or both, according to the peculiarities of the case. Dr. PEREIRA advises parts burned with phosphorus to be washed with a weak alkaline solution, to remove any phosphorous acid which may perpetuate the irritation.

196. vii. SALTS, CORROSIVE ALKALINE.—*Saline Caustics.*—Of the *alkaline salts*, the most

*corrosive* are the *bichromate of potash* and the *binoxalate of potash*. Several other alkaline salts, which have usually been arranged with corrosive poisons, exert their fatal influences otherwise than by any corrosive effect they produce on the digestive canal; this effect never amounting to more than irritation and inflammation, which are of themselves insufficient to cause death in the short period sometimes observed.

197. *A.* The *bichromate of potash* is extensively used in dyeing. Accidents may hence occur from it, although it may not be resorted to with suicidal or criminal intentions. In a case in which a strong solution of it was taken, burning pain in the throat, violent vomiting, and the other symptoms of corrosive poisoning, and death in five hours, were occasioned. On *examination* after death, extensive destruction of the mucous membrane of the stomach and small intestine was found. Dr. CHRISTISON remarks that, when this salt was first introduced into the art of dyeing, the workmen, who had their hands frequently immersed in its solution, were attacked with obstinate ulcers in the parts touched by it, and that these sores gradually extended deeper and deeper without spreading, until they actually sometimes made their way through the arm or hand.

198. *B.* The *binoxalate of potash*, when taken into the stomach, produces the same *symptoms* and *structural lesions* as have been described as the consequences of the ingestion of *oxalic acid*; and the treatment of instances of poisoning by the bichromate of potash, or by it, differs in no way from what has been advised for poisoning with that acid (§ 166).

199. viii. SALTS—METALLIC.—Several of these salts exert a corrosive action on the living tissues; and, when taken into the stomach, in states of strong solution or in substance, they destroy life chiefly in virtue of this action; but in smaller doses, and in weaker solutions, they act differently, are more or less abundantly absorbed, and produce effects which rank them under certain of the *classes* of poisons to be considered in the sequel. It is chiefly with reference to this corrosive and local action that I have here to notice them.

200. *A.* *Antimony.*—The several preparations of antimony liable to become poisonous, with the exception of the *chloride* (§ 175), act as irritant and depressing agents, and are therefore treated of in the *Class Aero-sedative poisons*.

201. *B.* *Bismuth—Subnitrate of—Magistery of Bismuth—Bismuthi trisnitas.*—Poisoning by this substance has rarely occurred. In the experiments of ORFILA, forty grains of the *nitrate of bismuth* introduced into the stomach of a dog produced all the symptoms of corrosive poisoning, and death in twenty-four hours; the villous coat of the stomach being reduced to a pulpy mass, and eroded in parts. The *subnitrate* was found to produce the same symptoms and lesions as the *nitrate*, but a much larger dose was required.

202. *a.* In a case in which the *trisnitrate* was taken, in the dose of two drachms, the patient was immediately attacked with burning pain in the throat, vomiting of brown matters, purging of watery stools, cramps, and coldness of the limbs, intermitting pulse; followed by inflammation of the throat, difficult deglutition, a constant nauseous metallic taste, hiccup, labori-

ous breathing, suppression of urine, swelling, and tension of the belly, salivation, delirium, &c. He died on the ninth day.

203. *b.* On inspection it was found that, from the pharynx to the rectum, there were but few points of the digestive canal free from change. The tonsils, uvula, pharynx, and epiglottis were gangrenous, the larynx spotted black, the gullet livid, the stomach very red, with numerous purple pimples; and the whole intestinal canal was red and gangrenous in places, especially at the rectum. The endocardium was bright red. Probably in this case there was partial absorption of the salt, which had thus inflamed the endocardium; if, indeed, the redness was not merely the result of *post-mortem* eoloration.

204. *c.* *Treatment.*—No chemical antidote is known to this poison. Emollient drinks should be given abundantly, and the poison evacuated from the stomach as speedily as possible by means of the stomach-pump, or otherwise. Afterward demulcent eneinata ought to be administered. A strictly antiphlogistic treatment should be adopted, to prevent inflammation, or to remove it if it have supervened. Opiates in full doses, camphor, and demulcents should also be exhibited.

205. *C. COPPER*.—The preparations and compounds of, are violent poisons; but, although they produce an active emetic effect when taken into the stomach, they act in large doses more upon the nervous system than locally, or as corrosive or caustic agents. These preparations have seldom been given with a criminal intention, owing to their acrid taste, unless with the view of producing abortion, and with this object the *sulphate* has been often taken. Poisoning by them is most frequently the result of accident. When swallowed in the largest quantities they sometimes occasion the least serious effects, owing to their instant rejection by vomiting. They, nevertheless, often produce, either most *acute* and virulent poisoning, or effects which are more slowly developed, thereby occasioning a *chronic* form of poisoning. Even in the most acute or rapid cases, the lesions they produce on the digestive canal may be the least remarkable, while in the slow or chronic form these lesions may be severe.

206. *a.* The symptoms, as respects the digestive organs, are nearly the same as in other instances of corrosive poisoning; but the vomiting is most rapid and copious, and the rejected matters present a remarkably *blue* or *green colour*, sometimes with minute or broken crystals of the salt. Abdominal pain is acute, and is attended by diarrhœa, extreme anxiety, and spasms of the extremities. *Jaundice* is sometimes met with: a symptom rarely observed in other cases of acute or corrosive poisoning. Stupor, coma, insensibility, convulsions, and sometimes paralysis, supervene early, and terminate life in periods varying from three or four hours to several days. In the more *chronic* states, these symptoms are developed and proceed more slowly; the discharges present a greenish hue, especially if verdigris have been taken, and the salt may be detected in them. The digestive canal evinces the most severe disorder: vomiting, copious eructations, salivation, diarrhœa, tenesmus, dysuria or suppression of urine, cramps, convulsions, prostration

of strength, &c., continuing for several days, or until death or recovery takes place.

207. *b.* On dissection, of the chronic cases especially, evidences of inflammation, in various parts of the digestive canal, have been found, generally attended by softening, tumefaction, ulceration, and more rarely with perforation of all the coats of the tube. These lesions are often more remarkable in the intestines than in the stomach. The digestive villous membrane presents a green colour, or even minute particles of the poison. These lesions are not constant; but the nervous system betrays, in the great majority of instances, marked functional disorder. Therefore, poisoning with the salts or oxides of copper will be farther considered under the *Class Acro-sedative Poisons*.

208. *c.* *Treatment.*—The chemical antidotes for the cupreous preparations have been stated by Dr. PEREIRA to be the whites of eggs, given abundantly, or whatever may contain most *albumen*. In the absence of eggs, milk or wheat-flour should be employed. *Iron filings* have been proposed by NAVIER, PAYEN, and CHEVALIER, and subsequently by DUMAS and ENWARDS; the iron decomposing the cupreous salt, and precipitating the copper in the metallic and inert state. The *ferrocyanide of potassium* is also said to be a good antidote; a drachm or two of it may be taken with safety. *Sugar* was proposed by M. DUVAL: its efficacy, although denied by ORFILA and VOGEL, has been recently contended for by POSTEL. (PEREIRA, *Mat. Med.*, vol. i., p. 776.)

209. The efforts of the stomach should, however, be promoted in order to procure the discharge of the poison; and, with this view, the whites of raw eggs, milk, warm mucilaginous drinks, &c., should be given frequently and liberally, and, as well as starch, administered as enemata. The stomach-pump may be of service in some instances; but, when vomiting follows freely and abundantly the ingestion of these draughts, it may be more injurious than beneficial. Inflammatory symptoms should be combated in the usual way, according to their severity and the peculiarities of the case. The nervous symptoms require a recourse to external derivatives, and the other means which will be mentioned in the sequel. (See *Class Acro-sedatives*.)

210. *d.* In the more *chronic* cases of poisoning with the cupreous compounds, opiates in full doses, with or without creasote and camphor, may be given in demulcent vehicles; or the sirup of poppies may be similarly exhibited or administered in enemata, and be aided by warm baths and external derivatives; but these means should not be resorted to until the poison has been evacuated from the stomach and bowels.

211. *D. GOLD*.—*Hydrochlorate of—Chloride of—Iodide of Gold*, and some other preparations of this metal, have been recently employed in medicine, especially on the Continent, and may, from accident or otherwise, occasion poisoning.—*a.* Dr. CHRISTISON states that the poisonous properties of the *chloride* are powerful, and closely allied to those of the hydrochlorates of tin and nitrate of silver. The chloride of gold occasions death in three or four minutes when injected into the veins, even in

very minute quantities, and the lungs are found after death so gorged with blood as to sink in water. (ORFILA, *Toxicol. Génér.*, t. i., p. 593.)

212. *b.* If the chloride of gold be *swallowed*, corrosion of the digestive canal takes place; and the salt is so rapidly decomposed that none is taken up by the absorbents; and death ensues from the local injury solely. Even in doses so small as a tenth of a grain, it has caused much irritation of the stomach. The form of fulminating gold has produced alarming poisoning where it was used in medicine. PLENCK says that it excites griping, diarrhœa, vomiting, convulsions, fainting, salivation, and sometimes even occasions death. HOFFMANN repeatedly saw it prove fatal, the most prominent symptoms being vomiting, great anxiety, and fainting. In one of the cases the dose was only six grains.

213. *c. Treatment.*—The *antidotes* for the preparations of gold are the same as those found most successful for poisoning by corrosive sublimate, especially the whites of raw eggs, or *albumen*, large draughts of milk, &c. The gastro-enteric symptoms should be removed by vascular depletions, derivatives, emollient enemas, warm baths, opiates, &c.

214. *E. IRON.*—None of the preparations of iron fall under the class of corrosive or caustic poisons, unless the *tincture of the sesquichloride*, and it owes its injurious operation, when taken in large quantities, to the excess of acid, the *symptoms* and *lesions* produced by it being the same as those occasioned by *hydrochloric acid* (§ 150).

215. *F. MERCURY.*—The *preparations* of this metal often cause poisoning, which may be either *acute* and *rapid*, or *chronic* or *slow*, according to the quantity taken, to the repetition of the doses, and to the modes of employing them. In large doses, the more active of these preparations act rapidly, and are corrosive and acute poisons; but, in small or repeated doses, their effects are chronic or slow, and they act as *acro-alterative poisons*, in which class I shall consider this mode of their operation, in connexion with that of some other preparations of mercury. It is thus chiefly the *acute* or *corrosive action* of these preparations which I have here to consider; the *chronic*, or consecutive effects, will fall under the class just referred to.

216. *a. The Bichloride of Mercury—Corrosive Sublimate.*—The poisonous operation of this substance has been ably investigated by ORFILA, CHRISTISON, PEREIRA, DEVERGIE, BECK, TAYLOR, and others. The *symptoms* caused by a large dose of the bichloride appear either immediately, or in a very few minutes after having been swallowed. A coppery or metallic taste is felt in the mouth; and if the poison be in a state of solution, sensations of remarkable acidity, burning constriction, and corrosion are felt in the mouth, fauces, and pharynx, descending to the stomach, where, in whatever state it may have been taken, pain is very soon occasioned by it; is increased on pressure, and is followed by nausea and vomiting, the matters thrown up consisting of the alimentary articles remaining in the stomach, and afterward of stringy masses of white mucus, streaked or mixed with blood. To these supervene difficult deglutition, the rejection of whatever is taken into the stomach; sometimes a sense

of strangulation or suffocation; the extension of pain over the abdomen, and intolerance of pressure; violent purging, and lacerating pains of the bowels, followed by tenesmus and mucous and bloody stools; anxiety, restlessness, and short or laborious respiration; a quick, small, and contracted pulse; burning thirst, and a white, dry, constricted state of the tongue and mouth; anxious expression of countenance, at first with flushing, subsequently with collapse and twitchings of the muscles of the face; suppression of urine or dysuria; cold sweats, great debility and sinking; sometimes pyalism; sinking and irregularity of the pulse; and coldness of the extremities. Death is often preceded by stupor, insensibility, convulsions, or twitchings of the limbs, or even by paraplegia.

217. Poisoning by this substance *differs* from that produced by *arsenic*: 1st. The well-marked taste, and the acidity and irritation of the throat and œsophagus, produced by the former, are much greater than by the latter; 2d. The symptoms are more violent and immediate upon the ingestion of this poison than after arsenic; 3d. The evacuations are oftener mixed with blood, and irritation of the urinary organs, or suppression of urine is more frequent than after poisoning with arsenic. The symptoms caused by corrosive sublimate resemble, in the most acute cases, and at the commencement, an attack of common *cholera*; subsequently, when the patient survives two or three days, they resemble those of *dysentery*, especially as respects the existence of tenesmus, and of mucous and bloody stools; and when pyalism, or affection of the salivary glands, is not present.

218. *b. Appearance after Death.*—These are confined chiefly to the digestive canal. The mucous membrane of the throat and œsophagus, and sometimes, also, of the mouth and fauces, is softened, and of a whitish or bluish gray colour; that of the œsophagus, especially near the cardia, is partially corroded. The villous surface of the stomach often presents a slate-gray or grayish tint, arising from the action of the poison, as supposed, upon this surface during life. Underneath, the tissues are more or less inflamed, sometimes in patches, and large black ecchymoses, or extravasations of blood, are often found underneath the villous membrane. In rarer cases this membrane is only simply inflamed. The coats of the stomach are corroded, discoloured more or less, and often softened so as not to admit of removal without laceration. Perforation, however, is very rare. Similar changes to the above are met with in the small intestines and in the large bowels, especially in the sigmoid flexure of the colon and rectum, but not to so great extent as in the stomach, although sloughing ulcers are more frequently met with in these latter situations. The colon is generally very much contracted. In cases which have not been very rapidly fatal, sloughing ulceration, dark discolouring of the ulcers or in their vicinity, and softening, are met with in several parts of the digestive canal. Various alterations of the urinary organs are occasionally observed; but these are neither constant nor uniform, with the exception of contraction of the urinary bladder, which is always observed. The epiglottis and trachea

are sometimes inflamed, and the endocardium often presents indications of inflammation. The coats of the stomach and intestines and the collatitious viscera often yield mercury on analysis. Poisoning by this substance does not delay the accession or progress of decomposition, as observed in respect of poisoning by arsenic.

219. *c. The quantity which may destroy life* varies greatly with the circumstances adduced above (§ 51, *et seq.*). The *smallest* quantity instanced by Mr. TAYLOR is *three grains*, this having been given to a child by mistake for calomel; but he believes that *two*, or not more than *three grains*, have proved fatal in an adult. If this quantity—even two grains—be taken at once on an empty stomach, I do not doubt that it is capable of producing a fatal result, if medical aid be not procured; but I state this chiefly from much experience of the medicinal exhibition and properties of this substance. When this poison has been taken on a full stomach, or when free vomiting has followed the ingestion of it, or when medical treatment was not long delayed, very large quantities have failed to produce death. A case is recorded by Dr. BOOTH (*Medical Gazette*, vol. xiv., p. 63), in which an *ounce* was taken, and, owing to these favourable circumstances, recovery was effected.

220. *d. The period at which death takes place* varies, in the *acute cases*, from two or three hours to five or six days. Mr. ILLINGWORTH (*Med. Gaz.*, vol. xxxi., p. 557) met with an instance of death from the sublimate in from two to three hours. Death from this substance in from ten to twenty-four hours is common; but life may be prolonged for several, or even many days, although the dose of the poison has been very large, when medical aid has been soon obtained. In these, the symptoms of *slow or chronic poisoning* have generally appeared; and the effects—ptyalism, diarrhœa, tenesmus, &c.—described in connexion with the *acro-alterative* action of this and other preparations of mercury, have usually been observed. *Acute poisoning* by this substance is the result of the chemical action, and the destruction of the tissues caused by the contact of it. The fatal issue is produced by the extent of lesion of the digestive canal, aided by the shock to vital power and nervous energy. Whatever absorption may occur in the circumstances more favorable to this mode of operation and in the more prolonged cases, will farther aid this issue, owing to the injurious influence which an excessive amount of the poison in the circulation will exert upon the heart and nervous masses.

221. *e. The treatment of acute poisoning* by corrosive sublimate consists of the *removal* of the poison, of the administration of *antidotes*, and the counteraction and removal of the effects produced.—(a) The *removal* of the poison from the stomach is best procured by the encouragement of vomiting by means of copious draughts of fluids, containing or consisting of the antidotes about to be noticed. Mr. TAYLOR states that, “if vomiting do not already exist, it must be promoted by the exhibition of emetics.” But it may be urged against this advice, that the circumstances are rare which admit of emetics; for they may increase the

mischiefs in the stomach, or otherwise complicate the case; or time may be lost in waiting for their operation, which may not soon take place, unless they are of an energetic kind. A recourse to the stomach-pump is liable to the objection already urged against it, in cases where the œsophagus and stomach are constricted, corroded, or softened by the poison (§ 174). Swayed by these considerations, I advise an immediate recourse to such draughts as are most likely to promote vomiting, and thereby the rejection of the poison, and to convey at the same time the *antidote* which may be obtained with the least delay.

222. (b) The *antidotes* are chiefly those which more or less efficiently decompose the corrosive sublimate: these are *albumen*, the *gluten* of wheat, *milk*, *iron filings*, and *meconic acid*.—*a. Albumen* appears to decompose the sublimate, so as to render it almost inert. Dr. CHRISTISON has adduced several cases proving the remarkable efficacy of this antidote. The celebrated Baron THENARD swallowed inadvertently a concentrated solution of corrosive sublimate; but by the immediate and abundant use of the whites of eggs, he suffered no material harm. Raw eggs—both the whites and the yolk—should be taken most abundantly, and ought not to be withheld, even although the poison has been taken for a considerable time; for this antidote is often efficacious notwithstanding, and is the one most to be depended upon. PESCHIER states that one egg is sufficient for every four grains of the poison; but no harm can result from taking many, as they will be thrown off by vomiting; indeed, they should be so given as to promote vomiting.

223. *β. Gluten* has also been recommended by Professor TADDEI. It may be prepared by washing flour in a muslin bag, under a current of water; but it will be preferable, when albumen cannot be procured, to mix flour in water, and give it in abundance: it will thus often promote vomiting (§ 221), and act as an antidote. *Milk*, in the absence of albumen or flour, may be likewise given, or *gum-water*, *linseed tea*, or sweetened water. *Iron filings* are stated to be useful, by reducing the sublimate to the metallic state. *Meconic acid* is also said to be an antidote, by forming an insoluble meconate of mercury. But, as Dr. PEREIRA justly remarks, a knowledge of this fact is of little practical value, since the acid is not generally procurable; and tincture of opium, which contains it, cannot safely be used in sufficient quantity; for Dr. CHRISTISON finds that five grains of corrosive sublimate require an infusion of thirty-three grains of opium to precipitate the whole of the mercury. Mr. TAYLOR states, that the *protochloride* of tin, in the proportion of one part to fifteen parts of water, has been recently proposed by M. POUJET as an antidote. But the efficacy of this substance has not been sufficiently tested in the human subject. These antidotes, even albumen, cannot be expected always to be successful. The sooner they are given the greater is the chance of success. Several instances, however, have been recorded of their failure, owing either to delay in their exhibition, or to the perfect solution and quantity of the poison, or to other circumstances of the case. Hence it will always be proper to exhibit the antidotes, as already advised (§ 222).

especially the eggs, in large number, and in the way most likely to promote vomiting.

224. (c) The effects produced by the poison, as far as these are indicated, should next attract the attention of the physician. These approach, in some cases, to the more common forms of gastro-enteritis, or of dysentery, or even of peritonitis; but the vascular action is generally less sthenic than in those, owing to the extent and severity of the injury sustained by the villous membrane and nerves of the digestive canal, and hence vascular depletions cannot be carried to the same extent as in these diseases. They are, however, generally required, most frequently locally by leeches, rarely by venæsection, or by both modes in the same case. Demulcents with opiates should be freely administered, and emollient and anodyne enemata be thrown up. Fomentations, rubefacient embrocations, &c., ought to be applied to the abdomen, and frequently renewed; and warm baths resorted to occasionally.

225. (d) The diet, as recovery advances, should consist chiefly of farinaceous articles, of light panada, gruel, demulcent drinks, milk, rice-milk, or creams, and broths made of the flesh of young animals; and flannels ought to be worn nearest the skin.

226. f. The *nitrate of mercury* are corrosive poisons. They are easily dissolved in water, especially if there be a little excess of acid present. Mr. BIGSLEY has recorded (*Med. Gaz.*, vol. vi., p. 329) the case of a boy who dissolved some mercury in a strong nitric acid, and swallowed about a teaspoonful of the solution. He was instantly seized with excruciating pain in the pharynx, œsophagus, and stomach; urgent anxiety, cold skin, small pulse, colic, and purging. He sank rapidly, and died in about two hours and a half. The fauces, œsophagus, and stomach were found, after death, corroded and inflamed. The treatment is the same for poisoning by these salts as for that by corrosive sublimate. The diluted proto-chloride of tin is suggested as an antidote by Mr. TAYLOR.

227. g. *Bicyanide of mercury* is a most active corrosive poison. A person swallowed twenty-three grains of this substance, and was immediately attacked with all the symptoms characterizing the ingestion of corrosive sublimate; and, on inspection after death, the same lesions of the digestive canal were observed. The treatment is also the same as that already recommended for poisoning by the sublimate.

228. h. *White precipitate*—the ammonio-chloride of mercury; *red precipitate*—the red oxide of mercury; *turbith mineral*—the subsulphate of peroxide of mercury; *cinnabar* and *vermilion*—the persulphuret of mercury; and *calomel*—the chloride of mercury, are severally acid poisons, in very large or repeated doses, and may even corrode the digestive canal; but their effects are uncertain as respects this mode of action, and therefore they will be more appropriately considered hereafter; when also poisoning by the external use of mercurial preparations, and by other modes of employing them, will be noticed.

229. G. SILVER—*Nitrate of—Lunar caustic*—is a powerful corrosive poison, when employed in substance or in strong solutions. It rapidly combines with, and is ultimately decomposed by the tissues, the acid corroding them. It is,

in these states, a local and disorganizing agent, and is not absorbed unless it be employed in small and frequent doses. There are very few cases of poisoning by it on record, and these have not been detailed with any precision.—a. The symptoms produced by this poison are most probably but little different from those caused by several other corrosive poisons; but, judging from its effects in large medicinal doses, diarrhœa is most probably not occasioned by it.

230. b. *Treatment*.—The antidote for nitrate of silver is common salt, which, acting upon the nitrate, forms nitrate of soda and chloride of silver, which is innocuous. The contents of the stomach should be removed, and the symptoms alleviated, by demulcents, opium, external derivatives, and local bleedings; by emollients containing salt, and by anodyne enemata.

231. H. TIN—the *Chlorides or Muriates of*.—A mixture of these is extensively used in the arts, and may hence produce accidental poisoning; but instances of such an occurrence are extremely rare. They appear to act as local corrosive poisons when taken in large quantity, and to occasion the usual symptoms of this class of poisons. They are decomposed by many organic substances, and then the treatment of poisoning by them should consist of the liberal and frequent ingestion of albumen, milk, and demulcents; and, after the stomach has been completely evacuated, of the administration of opium, emollient enemata, &c.

232. I. ZINC—*Chloride of*.—a. This substance, now employed as an antiseptic, when taken into the stomach, or applied to any living tissue, in states of strong solution, is a powerful caustic, or corrosive poison. It may be inferred to produce the usual symptoms of corrosive poisons, as I am not aware of an instance of poisoning having been caused by it; and its effects may be treated by the administration of the carbonate of soda, or any of the alkaline carbonates, with albumen, demulcents, and other means already recommended for caustic and corrosive poisons.

233. b. *Sulphate of Zinc—white vitriol*—has been considered as a corrosive poison; but its corrosive and local action is very rarely so great as to occasion death, even when given in very large quantity, for it is generally immediately thrown off the stomach, and occasions merely an irritant and astringent action; and, with reference to this action, it will be considered in the third class of poisons.

234. ix. VEGETABLE ACIDS.—There are numerous vegetable productions which produce poisonous, or at least injurious effects, when taken into the stomach; or when applied externally, or otherwise employed. Many of these act chiefly locally, inflaming and corroding the tissues; while others produce less local irritation, but are absorbed to a greater or less extent, acting thus remotely and injuriously upon the nervous centres and on vital organs. Under this class, I shall very briefly notice such of the vegetable poisons as act chiefly on the digestive villous surface when swallowed, and locally as respects the parts to which they may be applied.

235. a. *Anemone nemorosa*—A. *pratensis*—A. *Pulsatilla*, and A. *sylvestris*, are severally very acid poisons. BULLIARD states that an old man with rheumatic gout applied the bruised root of A. *Pulsatilla* to the calf of his leg on going to bed; violent suffering, with sphacela

tion of the part, ensued. Animals have exhibited marks of intense inflammation of the stomach and rectum after having swallowed it. *A. nemorosa* is said to produce dysentery in sheep. The inhabitants of Kamtschatka make use of this plant to poison their arrows. ROBERT and VAUQUELIN extracted a fluid of an acrid taste and pungent odour from the flowers of the *A. pratensis*, which acted like a caustic on the tongue.

236. *b. Arum maculatum*—Wake-robin—*A. Dracunculus*, and other species of arum are acrid poisons in the recent state, and when not acted upon by heat. They occasion a burning pain and swelling in the throat; difficult and painful deglutition. BULLIARD states that three children, who ate of the leaves of the *A. maculatum*, were thus affected, and experienced horrible convulsions. Two of the three died after some days. The *Calla palustris*, or *Water Arum*, excites a similar action to the above.

237. *c. Bryonia dioica*—*Bryony*.—The root of this plant occasions vomiting, violent pain, profuse alvine evacuations, and faintings. PYL mentions a fatal case from taking two glasses of an infusion of the root to cure an ague. TORMINA and purging soon supervened, and killed the patient. It occasions violent inflammation in the large and small intestines, and of the stomach. BRANDES imputes the acrimony of the plant to a principle which he has called *bryonine*, which induces intense inflammation of the parts to which it is applied.

238. *d. Caltha palustris*—*Marsh Marygold*—has been noticed by several writers as an acrid poison, inflaming the œsophagus, stomach, and bowels, even of the lower animals. A family of five persons in Germany, after partaking of it, were all seized, in half an hour, with pain in the stomach, sickness, vomiting, diarrhœa, and dysuria; and, on the following day, with a general swelling of the body, and a copious eruption. They, however, all recovered. In addition to the inflammatory action produced by it in the digestive canal, it appears to be absorbed, and to occasion general vascular excitement, and irritation of the urinary organs and skin.

239. *e. Chelidonium majus*—*Celandine*—has a bitter and acrid taste, and causes inflammation of whatever parts to which it may be applied. When taken into the stomach it inflames the digestive mucous surface, and is partially absorbed; exciting the brain and nervous system; and causing congestion of the lungs. These latter effects, especially that on the brain, are more remarkably produced by *C. Glaucium* *Clematis Vitalba* (*Virgin's bower*)—*C. Flammula*—*C. erecta*—*C. integrifolia*, are all acrid and caustic. When applied to the skin, they produce redness, pustules, and excoriations. STORCK and MUELLER prescribed them in some chronic affections, especially syphilis, rheumatism, and scrofula, in small doses, in the form of infusion; continuing their use for some weeks with alleged benefit. M. ROQUES states that they occasion dysentery in animals. The powder of the leaves, in doses of one, two, or three grains, has also been employed. They are exciting, diaphoretic, and alterative in small doses; but in large doses they destroy life, by the intense inflammation they produce in the whole course of the digestive canal.

240. *f. Croton Tigulum*—*Purging Croton*.—

The seeds of this plant have a burning, acrid, and nauseous taste. They were formerly employed as a hydragogue-purgative; but, on account of the violence of their operation, were laid aside. One seed is sufficient for a dose, and even sometimes excites violent vomiting and purging. More recently the *expressed oil* of this plant has come into use. Dr. PEREIRA met with a case of poisoning by inhalation of the dust of the seeds. The patient had been employed for several hours in emptying packages of the seeds. He complained of loss of appetite, of a burning sensation in the nose and mouth, followed by pain at the epigastrium, and copious lachrymation. He became giddy and insensible, but recovered. His bowels were not affected.

241. The oil causes rubefaction, and a vesicular or pustular eruption, when rubbed on the skin; and when rubbed on the abdomen, it often purges. When swallowed in one or two drops, it produces a burning acrid taste in the mouth and throat, and acts as a drastic purge, procuring watery motions, and sometimes an increased secretion of urine. It appears to be partially absorbed; but it evidently acts as a sedative irritant of the digestive mucous surface. The only case of poisoning which is known to have been caused by it was that of a young man, ill of typhoid fever, who took by mistake two and a half drachms of the oil. Three quarters of an hour afterward the skin was cold, and covered with a cold sweat; the action of the heart and pulse was scarcely perceptible; the respiration difficult, and the extremities blue. An hour and a half afterward there were excessive involuntary alvine evacuations, but no vomiting; the abdomen was tender to the touch; and a burning sensation was felt in the œsophagus. The blueness extended over the body; the surface became insensible, and death took place after four hours. This oil, even in the usual purging dose, sometimes acts violently, generally speedily, although not certainly, occasioning much depression of the vascular system, and a feeling of debility.

242. *g. Cucumis Colocynthis*—*Bitter Apple*.—The spongy or medullary part of the fruit is a drastic cathartic, causing inflammation of the villous surface of the bowels, and bloody evacuations. This substance has caused death in several instances owing to mistake. A woman swallowed a teaspoonful and a half of colocynth powder, and died in twenty-four hours. A person took two glasses of a decoction of colocynth, and died in a short time. VAUQUELIN discovered the active principle of this plant, and called it *colocynthin*.

243. The *symptoms* are, at first, frequent alvine evacuations; great heat and colicky pains in the bowels; dryness of the throat, and unquenchable thirst; a small and rapid pulse; redness of the tongue; a fixed pain around the umbilicus, and tenderness. To these succeed coldness of the extremities, cramps, sinking of the powers of life, and death. On *dissection*, the whole digestive canal exhibits marks of inflammation, which is often most intense in the stomach and large bowels, the villous membrane of which is abraded, readily detached, or even ulcerated. The intestines are studded with black spots or ecchymoses; the inflam-

mation sometimes extends through all the coats; the peritoneum being inflamed, and either adherent to its opposite surfaces, or covered by a false membrane, or containing a whitish fluid and florenti.

244. *h. Cyclamen Europæum* is a violent irritant, exciting vomiting and purging. BULLIARD states that its root produces cold sweats, dizziness, and convulsions; the patient voids blood both by vomiting and by stool, the super-purgation and inflammation proving even fatal.

245. *i. Daphne Gnidium* (*Spurge-flax—Flax-leaved Daphne*)—*D. Mezereum* (*Mezereon*).—The bark of these plants acts as a corrosive poison when applied to living tissues. I have frequently employed the mezereon bark as an external irritant, instead of caustic alkali, in forming an issue. When swallowed, it inflames the digestive canal, causing heat and dryness of the throat; salivation, abdominal pains, frequent vomitings, bloody stools, giddiness, and feebleness of the limbs; and the lesions above described (§ 243). The *Daphne Laureola* is also poisonous, and produces nearly the same effects as the other species.

246. *k. Delphinium Staphisagria—Stavesacre—Palmated Larkspur—D. tricornis*.—The acrid property of these plants is lodged in the alkaloid, which LASSAIGNE and FENEILLE discovered in them, and which is an extremely acrid irritant. The local effects of these plants are evidently the most striking. They have been found to inflame intensely the digestive mucous surface when swallowed, but not to produce any alteration of other organs.

247. *l. Euphorbia Officinaria*.—The stalk of the various species of the genus *Euphorbia* furnishes a milky juice, which, on being dried, is called *euphorbium*. It is a gum-resin, which contains an active principle, styled *cuphorbin*. A teaspoonful of the gum-resin was administered by mistake; and it occasioned a burning sensation in the fauces and throat, rapidly extending to the stomach, and causing incessant watery vomitings. The pulse became remarkably rapid and irregular; a cold perspiration broke out, and death took place after two days. The body was inspected eight hours after death; the coats of the stomach could be torn with the greatest ease; the internal surface of the viscus was studded with gangrenous spots; the spleen was enlarged and much softened, and the inner coat of the aorta was beautifully injected with blood, and highly inflamed. The after lesion was probably caused by the partial absorption of the poison in this case.

248. Many of the species of the genus *Euphorbia* are poisonous, as the *antiquorum*, *canariensis*, *Tirucalli*, *Peplus*, *helioscopia*, *verrucosa*, *platyphyllos*, *palustris*, *hibernica*, *amygdaloides*, *sylvatica*, *exigua*, *mauritanica*, *neriifolia*, *Esula*, *heptagona*, &c., and have been employed in poisoning spears, arrows, &c. The species *Lathyrus* and *Cyparissias* are said by LAMOTTE to have proved fatal when administered in a *glyster*. A person allowed his closed eyelids to be rubbed with the juice of the *E. Esula*: inflammation took place, and it was followed by the loss of the eye. A boy six years old ate some of the *E. Peplus*. It produced vomiting, purging, spasms, a weak, small pulse, inability to swallow, insensibility, cold extremities, and death. On dissection, the tonsils, fauces, and

pharynx were seen very much inflamed. The villous membrane of the stomach and small intestines were very red; but that of the large intestines much less so. The urinary bladder was very contracted. The epiglottis and larynx were highly inflamed. The lungs were healthy. The veins of the dura mater were congested. The blood was fluid. The brain was healthy.

249. *m. Gratiola officinalis—Hedge Hyssop*—acts chiefly locally, causing inflammation of the part which it touches. It has produced death rapidly when an extract of it was injected into the veins.

250. *n. Hippomane Mancinella—Manchineel-tree*.—The wood of this tree, when green, excites inflammation of the skin when rubbed against it. The dust of the wood is so acrid as to excite inflammation of the respiratory passages, or asphyxia, when inhaled with the air. Dr. R. MADIANNA found that the juice excited inflammation when applied even to the sound skin. ORFILA and OLLIVIER applied this juice to a wound in the cellular tissue with a fatal result. When given internally, it soon destroyed life; the stomach and intestines being found, on dissection, very highly inflamed.

251. *o. Jatropha Curcas—Indian Nut*.—The seeds of this plant are a violent poison, exciting incessant vomitings, purging, severe pain, vital depression, and death. Its fatal effects are more rapid when it is taken into the stomach than when introduced into the cellular tissue. When swallowed, it produces intense inflammation of the digestive canal. Mr. BENNETT states that it is used as a purgative by the natives of the Philippine Islands, an over-dose producing intense pain, vomiting, and purging; their only antidote being large draughts of cold water.

252. *p. Juniperus Sabina—Savine*.—The leaves and tops of this plant contain an acrid poison, in the form of a volatile oil of a remarkable odour. They are acrid and irritant in the state either of infusion, powder, or tincture, and yield a light yellow oil, in which the active properties of the plant chiefly reside. The powder, or the infusion, or the oil has been often taken in excessive doses, in order to procure abortion, the power of accomplishing which effect it does not possess more than any other violent irritant. When employed with this intention, it not unfrequently destroys the life of the mother, and sometimes even before an abortion is procured. Mr. TAYLOR states that in a case in which the savine powder was taken with a fatal issue, he found a green fluid in the stomach, which, with the œsophagus and small intestines, was highly inflamed. The poison was identified by placing the minute portions of the leaves found in the stomach under a powerful microscope. A girl, to procure abortion, took a strong infusion of savine leaves, which produced violent pain in the abdomen and strangury. She miscarried two days afterward, and died four days after that. On dissection, extensive peritoneal inflammation was found. The inside of the stomach was very red, and checkered with patches of florid extravasation (CHRISTISON, *Op. Lat.*). While this substance acts locally, it is also partially absorbed, and, through the medium of the blood and urine, affects the urinary organs.

253. *q. Momordica Elaterium*.—Wild or Squirt-  
ing Cucumber.—The fecula deposited by the  
expressed juice of the fruit of this plant—*elaterium*—contains the active principle to which  
the properties of the plant are imputed, and are  
chiefly, if not altogether, owing. Drs. CLUT-  
TERBUCK, PARIS, MORRIES, and PEREIRA have  
examined this fecula, and found that its active  
principle—*elaterin* or *momordicine*—which is  
soluble in alcohol, is a very active purgative in  
the dose of one twentieth of a grain. *Elaterium*—the fecula of the juice of the fruit—  
when of the best quality, is a drastic and hydra-  
gogue purgative in the dose of the one twelfth  
of a grain. Its acridity is such that it inflames  
and ulcerates the fingers of those who pre-  
pare it. Although acting thus energetically as  
a local irritant, it appears also to be partially  
absorbed, and even to have its irritant action  
transmitted by means of the nervous system  
to parts more or less remote. When taken in  
a large dose, it produces violent hypoca-  
tharsis and very copious watery stools, being the  
most energetic hydrogogue purgative known.  
Even a quarter of a grain of the purest kinds  
of *elaterium* may produce this effect and pro-  
cure the discharge of several pints of fluid by  
the bowels. An over-dose occasions not mere-  
ly violent griping pains in the abdomen, but  
also increased frequency of pulse, a dry tongue,  
great thirst, and dampness and coldness of the  
skin. A female took, by the advice of a quack,  
in divided doses, two grains and a half of *elaterium*  
and sixteen of rhubarb. They produced  
incessant vomiting and purging, which did  
not yield to treatment. She died in thirty-six  
hours. On dissection, the villous membrane of  
the stomach and intestines was intensely in-  
flamed. The colon was contracted: the other  
viscera were healthy. (*Boston Med. Mag.*, vol.  
iii., p. 25.)

254. *r. Narcissus Pseudo-narcissus*.—*Daffodil*  
—*Meadow Narcissus*.—The extract of this plant,  
applied either externally or internally, produces  
violent retchings, followed by death, owing to  
intense inflammation caused by it in the stom-  
ach and intestines, even extending to the rec-  
tum.

255. *s. Ranunculus*.—Several species of this  
genus of plants are remarkably acrid and cor-  
rosive, especially the *R. acris*, *R. sceleratus*, *R.*  
*Flammula*, *R. arvensis*, *R. bulbosus*, *R. alpestris*,  
*R. aquatilis*, &c. The leaves, flowers, and ex-  
pressed juice irritate, inflame, and ulcerate the  
external surface, according to the duration of  
their application; and, when swallowed, they  
excoriate the tongue, mouth, and throat; cor-  
rode and inflame the stomach, and tumefy the  
oesophagus and pylorus, occasioning extreme  
pain, retchings, &c. (PLENCK.)

256. *t. Rhus Toxicodendron*.—*Poison Oak*.—  
*Poison Ivy*.—FONTANA, ALDERSON, BARTON,  
BIGELOW, and others, have noticed the intense-  
ly poisonous action of this and several other  
species of the genus *Rhus*. A small portion  
of the milky juice applied to the skin excites  
burning, swelling, inflammation, and small ves-  
icles containing a sharp transparent humour;  
and nearly the same symptoms are produced  
by touching the leaves. Dr. ALDERSON states  
that sphacelation has followed contact with the  
acid juice of this plant in some cases. Drs.  
CUTLER and BIGELOW mention various noxious

effects to have followed the handling and the  
burning of the wood of the *Rhus vernix*, or *poi-  
son sumach*. The inflammation produced by the  
several poisonous species of this genus appears  
to present peculiar characters, with a marked  
disposition to diffusion, tumefaction, and gan-  
grene, or to assume the form I have described  
when treating of *diffusive inflammation of the*  
*CELLULAR TISSUE*. The leaves and juices of  
these species have been employed in medicine  
as excitants, and are supposed to produce not  
only intense irritation, but also considerable  
stupefaction; and hence it may also be consid-  
ered as a powerful *acro-narcotic poison*. (See  
CLASS VIII.)

[Poisoning by the *Rhus vernix* is very com-  
mon in the United States, and may occur from  
touching or smelling any part of the plant, and  
some individuals are so susceptible as to be  
affected by the volatile vapour which escapes  
from it: others handle the plant with impunity.  
The cutaneous inflammation caused by it  
will generally yield to a wash of sub-borate of  
soda (horax) or acetate of lead. In cases we  
have witnessed, inflammation appeared on the  
skin, in large blotches, in about 48 hours after  
exposure to it; chiefly on the face and extremi-  
ties; soon after, small pustules appeared on  
the inflamed parts, and became filled with wa-  
tery matter, attended with an almost insup-  
portable itching and burning. In two or three  
days the eruptions suppurated, after which the  
inflammation subsided, and in a short time the  
ulcers healed.]

257. *u. Stalagmitis Cambogioides*.—*Habraden-  
dron Cambogioides*.—The gum-resinous exuda-  
tion from this plant occasions, in large doses,  
nausea, vomiting, griping pains of the bowels,  
copious watery stools, &c. In excessive doses  
it acts as an acrid poison. A drachm caused  
horrible retchings and purging, followed by syn-  
cope and death. The fatal effects consequent  
upon taking a great number of MORISON'S pills  
have been owing to the gamboge contained in  
them. The symptoms in these cases were vom-  
iting and purging, pain and tenderness of the  
abdomen, coldness of the extremities, and sink-  
ing of the pulse. On examination *post mortem*,  
inflammation, ulceration, and sphacelation of  
the intestines were found.

258. *v.* There are many other plants, as sev-  
eral species of the *Rhododendron*, *Pedicularis*,  
*Plumbago*, *Phytolacca*, *Ricinus*, *Sambucus*, *Sed-  
um*, *Tanacetum*, *Pastinaca*, &c., which possess  
very acrid properties, and which, when taken  
into the stomach, occasion symptoms and le-  
sions similar to those caused by the plants al-  
ready mentioned. Others produce not merely  
more or less inflammation and excoriation, but  
also other functional and organic changes,  
which rank them in the classes which follow.

259. *y.* 1st. The action of the acrid vegeta-  
bles is generally exerted upon the tissues with  
which they come in contact, in which they oc-  
casion inflammation, excoriation, or corrosion,  
ulceration or sphacelation, with the symptoms  
usually attending these lesions, according to the  
parts in which they are produced. 2d. The fa-  
tal effects of these poisons are more certainly  
developed when they are taken into the stom-  
ach than when applied externally, or intro-  
duced into the cellular tissue; for, in the former  
case, they affect a greater extent of surface,

having an intimate connexion with the organic class of nerves, and, through these nerves, developing a wider range of morbid symptoms than in the latter. 3d. Some of these poisons, in addition to these local effects, are partially absorbed, and produce changes either functional or structural—nervous or vascular—in other remote organs, as the lungs, the urinary organs, the nervous masses, &c.

260. *z.* The treatment of the vegetable acids consists chiefly of the expulsion of them by encouraging vomiting, by means of mucilaginous draughts; and of allaying irritation by opiates, external derivatives, emollient and anodyne enemata, and local depletions. Opium may be given in full or frequent doses, and rubefacient embrocations or fomentations assiduously applied over the abdomen. I have found the turpentine fomentations, opiates, starch enemata, with the compound tincture of camphor or sirup of poppies, the most generally efficacious; and, if vital depression supervene, camphor, ammonia, decoction of cinchona, or aromatic infusions are the most serviceable. During recovery, the diet and regimen advised during convalescence from the effects of several corrosive poisons should be adopted (§ 157–174).

261. CLASS II. DEPRESSING AND PARALYZING POISONS—SEDATIVE POISONS.—There are several agents which destroy life by the extent to which they abstract the vital caloric, depress the nervous energy, and lower the action of the heart and vascular system generally. In virtue of these modes of operation, they destroy vitality without any very obvious pre-existent excitement, and without producing either the appearances or the symptoms or lesions attending local irritation. The effects of these agents are manifested by the states of function and of vital manifestation and action, and by no farther lesion than may be attributed to failure or loss of function or action; by the absence of such structural changes as are calculated to account for death, conformably with our acquaintance with the extent and consequences of pathological conditions. Of this mode in which certain poisons act, I have already taken a general view (§ 28–30). I shall, therefore, notice as briefly as possible those agents which come under this class—which destroy life by acting in this way, and independently of such structural lesions as are of themselves calculated to produce the result. It may, however, be here remarked, that there are numerous substances which, in addition to more or less manifest lesions of structure produced by them, act also as sedatives or depressants of nervous energy and vital action, which produce more complicated effects or associated results, and which thereby constitute other classes of poisons, more especially the fifth class.

262. *A.* ACETIC ACID, in various states of concentration or purity, may be so employed as to act as a sedative. It has been considered above (§ 125) with reference to its corrosive operation, or to its employment in larger doses, and in states of strong concentration. But when taken in states of dilution, and when the use of it is continued for a considerable time, it acts not only as a sedative, but also as a slow poison. These effects depend in some degree on constitution, and the quantity of it usually taken; for, in moderate doses, both

it and the mineral acids are tonics and refrigerants, and increase the appetite, while in larger doses, or when too long continued, they impair or otherwise affect the assimilating processes, and even change the constitution of the blood. When very dilute acetic acid is taken, especially during vascular excitement or in febrile states, it allays thirst, lowers the heat of surface, and increases the urine. It is certainly absorbed to a greater or less extent; and, both locally and through the medium of the circulation, it exerts some degree of astringent action. I have met with several instances of disorder from the protracted use of this acid, amounting nearly, and in one quite to that observed in the following case: A young lady enjoyed good health, was plump, had a good appetite, but was afraid of becoming too fat. She was advised to drink a small glass of vinegar daily: she did so, and her plumpness diminished; but, after some weeks, she began to complain of a short, dry cough; her body became lean and wasted; her breathing short and difficult, and the usual symptoms of tubercular consumption supervened. On dissection, all the lobes of the lungs were studded with tubercles. The long-continued use of acetic acid seems to favour the development of several organic changes which originate in debility. MORGAGNI believed that it favoured the production of schirrus of the pylorus.

263. *B.* ACIDS—THE MINERAL.—The action of these acids in large quantities, and in strong and concentrated states, has been already considered (§ 132, *et seq.*); in which states they act locally and as corrosives. But in states of weak dilution they operate differently, their effects varying with the quantity and continuance of the use of them. Many years ago I made a series of experiments with these acids in different states of dilution, and for various periods; and most of them were made upon myself. I found, 1st. That the sulphuric, the nitric, and the hydrochloric acids were severally absorbed into the circulation when taken in states of dilution short of producing corrosive effects. 2d. That, after periods varying with the amount and frequency of the dose, and with the acid taken, the presence of the free acid could be detected more or less abundantly in the urine. 3d. That sulphuric acid appeared sooner in the urine than the nitric or hydrochloric, and that the nitric required the longest time to appear, and the largest doses; but as to this particular, I was not quite satisfied. 4th. That the sulphuric acid evinced the most decided refrigerant and sedative action, especially when much diluted. 5th. That the use of these acids was at first tonic and refreshing, and to some extent astringent and diuretic; but that, when continued for some time, and when they were more abundantly absorbed, especially the sulphuric, they then were depressing; occasioning indigestion, weakness of the pulse, and in my own case, after the sulphuric acid had been taken some time, intermissions of the pulse, and impaired impulse of the heart, the urine at this time containing free sulphuric acid, or this acid in excess. 6th. That a too long continuance of these acids, particularly of the sulphuric acid, not only impaired digestion and assimilation, but also weakened the heart's action, lowered irritability, caused emaciation, disordering the bowels, and the secre-

tions poured into the digestive canal. 7th. That these acids act as refrigerant tonics only when employed for a short time in such quantity as may render drinks agreeably acid; that they are most beneficially prescribed in this manner, in order to remove a particular diathesis or specific condition; and that they are slow poisons when long continued in healthy states of the frame, the good effects often imputed to them resulting either from other causes, or from vital resistance and the efforts of nature. 8th. They affect, when continued for some time, the constitution of the blood. 9th. The mineral acids, when thus employed, are excreted from the blood chiefly by the kidneys and the skin.

264. *C. ALKALIES AND THEIR CARBONATES*, when taken in states of weak solution, or continued for too long a time, or in doses short of producing the effects described above (§ 167, *et seq.*), impair more or less remarkably vital power and vascular action. These substances are readily absorbed into the circulation, whence they are eliminated chiefly by the kidneys, and slightly by the skin. The prolonged use of them may occasion slow or chronic poisoning, owing to the effects produced by them on the digestive mucous surface, and on the urinary organs; for they manifestly favour the too rapid detachment or exfoliation of the epithelium covering the villous and mucous membranes of these viscera, while they alter the constitution of the blood, and affect the healthy states of the hæmato-globulin. When thus improperly employed, their operation as sedatives tends rather to favour the origin and development of organic lesions and chronic diseases, which may ultimately terminate life, than to cause death in a more direct and immediate manner.

265. *D. COLD*.—The abstraction of animal heat may, from its intensity or continuance, destroy life. Cold is a powerful sedative; hnumbing the sensibility, weakening muscular motion, and lowering vascular action. It also favours internal congestions, especially of the lungs, brain, and liver, and ultimately of the large veins and right side of the heart; these congestions increasing the effects of cold on the sensibility and on the vascular system to a fatal amount, unless judicious means of counteraction be adopted. The fatal effects of cold are favoured by repose; by the drowsiness, somnolency, or lethargy which it induces, and by a passive submission to this feeling; by previous excesses in spirituous liquors or intoxicating drinks, or even by the use of those at the time of exposure, if active exercise be not taken. But it is unnecessary to pursue the subject farther at this place than to associate its effects with other injurious agents, for the purposes of diagnosis, and of comparison with the action of other sedatives, or even with narcotic poisons, as this agent has been noticed above (§ 28, 29), and specially treated of with reference to its effects and treatment. (See *art. COLD*.)

266. *E. DIGITALIS*.—*Digitalis purpurea* has been usually classed with narcotics, or aer-narcotics; but it is more properly a sedative than a stupefying agent, as this latter property is either not at all, or imperfectly evinced; and whatever narcotic effect may be considered as actually produced by it, in any instance, is to

be imputed entirely to the depressed, paralyzed, or departing manifestation of cerebral function. The irritation caused by digitalis in the digestive canal is not great, does not proceed to inflammation, and is attended by marked depression of vital power. The effects produced by it on the heart obviously depend upon the quantity taken, the rapidity of its absorption, or the accumulation of it in the system, and upon the other peculiarities of the case, and particularly upon those connected with the constitution of the patient. In many its ingestion, even in a very large and poisonous dose, produces acceleration of the pulse—sometimes remarkable acceleration; but the pulse is always then weak, compressible, or small, the acceleration being manifestly, as in other cases of great quickness of pulse, an evidence of extreme depression of organic nervous influence and vital power. But, as the irritability of the heart and other muscular parts become impaired with the depression of the organic nervous influence upon which it depends, the increased frequency of the heart's action, if it have occurred, subsides more or less rapidly into remarkable slowness and irregularity, with or without intermissions, until the action ceases altogether.

267. The noxious operation of digitalis is manifested in all animals. One drachm of the powder acts as a sedative in horses affected with inflammation. Two ounces destroyed this animal in twelve hours. The influence of this poison on the heart of the horse is various. At first, the action of this organ is sometimes accelerated; in other instances it is not affected; and in some it is retarded. It generally occasions diminished muscular power, convulsive movements, tremours, and loss of sensibility. Of the numerous writers who have discussed the operation of digitalis, there is none who has estimated it so accurately as Dr. PEREIRA, or at least so conformably with my own experiments, and with my observations of its effects during a period of thirty years. Many years ago, I tried the effects of it upon myself in large doses, in different forms of preparation; and in practice I have pushed it, in some instances, as far as appeared compatible with the safety of the patient.

268. *a. Symptoms*.—Dr. PEREIRA has distinguished three grades of operation of foxglove, or of poisoning by this plant; and I shall adopt the division.—(a) *The first degree* is that usually produced by small and repeated doses, and consists chiefly of nausea or loss of appetite; of alteration of the heart's action and of the pulse, which becomes irregular, or accelerated, or slower than natural; of depression of spirits, of impaired strength, and of increased secretion of urine. These symptoms observe no regular order, sometimes the diuresis, at others nausea, and occasionally the affection of the circulation being the first to appear. The influence of digitalis on the circulation is by no means uniform. In some cases the pulse is accelerated or rendered full and soft; in others it is slower or irregular; in many it is intermittent; and in others it is not materially affected. A small dose, in some instances, reduces the frequency of the pulse, and renders the pulsation irregular or intermittent, or both; while a very large dose may be taken without any material effect upon the action of the heart.

In the summer of 1816, I took, while in good health, two drachms of the tincture at one dose; and, finding no farther effect from it than loss of appetite and slight depression, I took another drachm three hours afterward. I find in my note-book that the pulse was not affected by it during that and the subsequent day, farther than it was readily accelerated by the least exertion, and that very slight nausea, but no drowsiness, was produced by it. Dr. WITHERING, in one case, found the pulse fall to 40 pulsations in a minute, and Dr. Fogo, in another, to 36. The lowest I have seen it from the use of foxglove was 44; but 50, or even lower, is not infrequent. The slowness is sometimes preceded not only by acceleration, but also by increased fullness and softness. Even when the pulse is much slower than natural, in the recumbent posture, it generally rises very remarkably above the usual frequency in the sitting, and still more in the standing position. This is owing to the weakened state of the heart, caused by the digitalis, an increased frequency of contraction being required to compensate the loss of power, especially in positions unfavourable to an abundant supply of blood to the brain, by which the cerebral energy may be developed and the nervous influence of the heart thereby re-enforced and increased. This effect of position upon the action of the heart of a person under the influence of digitalis should be kept in recollection, and he should not be allowed suddenly to assume a sitting or standing posture; for the heart, already remarkably weakened, is unable to act sufficiently, or to overcome the increased obstacle which either of these postures furnish to it, especially when it loses the usual supply of cerebrospinal nervous influence, or even when it experiences a diminution of that supply. Owing to these conditions, and to insufficient attention being paid to them, a patient may be seized with fatal syncope while he is under the operation of this substance; and there is every reason to believe that this occurrence has actually taken place oftener than once in these circumstances.

269. The influence of digitalis on the pulse is more remarkable in debilitated and anæmiated persons than in the plethoric or robust. Sometimes no effect is produced on the pulse in respect of number, force, or regularity, until nausea, vomiting, or headache is experienced; and occasionally a comparatively moderate dose may occasion these symptoms. SHROEK, as quoted by PEREIRA, experienced from two grains of foxglove nausea, headache; small, quick, and soft pulse; dryness of the throat; giddiness, weakness of the limbs; and some hours afterward his vision became dim, with a sensation of pressure on the eyeballs.

270. The cumulative effect of digitalis is one of the most important facts to be kept in view in connexion with the use of small and repeated doses of this plant. After an indefinite time, during which the foxglove has been thus employed without any very marked effect, or with a slight effect merely, dangerous symptoms, in some instances terminating in death, have suddenly appeared. These generally consist of remarkable irregularity, frequent intermissions, or extreme weakness and slowness of the heart's action; giddiness; pallor of the coun-

tenance; nausea; vomitings; watchfulness; impaired sensibility; and sometimes convulsions. Dr. PEREIRA and Dr. HOLLAND, however, consider this emulative effect very rare. But this depends upon the time during which the digitalis has been exhibited, and the amount of the dose.—Early in the present century, when this plant, especially the infusion of it, was given in large doses, and very indiscriminately, in dropsies, I met with several instances of the cumulative operation of it in most dangerous forms; and two of these occurred in patients for whom I had myself prescribed it, and in whom I had watched its effects. One of these perfectly recovered from both this operation of the remedy and from the disease for which it was prescribed (dropsy); the other also recovered from this effect, and was partially benefited by the medicine; but the disease—tubercular consumption—ultimately terminated as usual. Salivation is an occasional consequence of the use of digitalis in repeated doses; and it may occur even after a few moderate doses, as noticed by WITHERING, BARTON, PEREIRA, and myself.

271. (b) *The second grade* of poisoning by digitalis is that which is most frequently produced by too large or too long-continued doses. The symptoms are described with great accuracy by Dr. PEREIRA. They are usually nausea or actual vomiting, slow and often irregular pulse, coldness of the extremities, syncope, or tendency to it, giddiness, confusion of vision, and loss of muscular power. The sickness is sometimes attended by purging, but oftener by dysuresis, occasionally by neither. The patient complains of a sensation of weight, pain or throbbing of the head, especially the forehead; of giddiness, of weakness of the limbs, and watchfulness. He sees objects dimly, or of a green or yellow hue; or he sees motes, sparks, or mists before his eyes. The pulse is feeble, sometimes accelerated, at other times slow, but is affected by the slightest exertion. There is remarkable tendency to syncope upon raising the head from the pillow, and to profuse cold sweats; sometimes delirium, stupor, salivation, and loss of sensibility supervene. There is much difficulty in assigning the quantity of the drug capable of producing these effects, whether taken in a single dose or in divided quantities. Much will depend upon the state of the plant, the kind of preparation, and the constitution of the patient. I may, however, here state, as the result of experiment and observation, that very large doses—three or four times the usual doses of either of the preparations, or even more—may be given without any effect during inflammatory action; that febrile excitement, physical exertion, and a high range of temperature seem to suspend the action of even very large quantities of the drug; while the depressing passions, cold, the contemporaneous use of antimonial preparations, of colicium, or of refrigerants, manifestly accelerate and heighten their effects.

272. (c) *The third or fatal grade* of poisoning by digitalis is characterized by retchings, purging, griping pains in the bowels, remarkable faintness, cold sweats, anxiety, and depression of spirits, collapsed features, vertigo, dilated pupil and disordered vision; a slow, feeble, irregular, and small pulse; extreme physical de-

pression and exhaustion, inability to sustain a sitting or upright posture, involuntary evacuations, low delirium, insensibility, convulsions, stupor, and death.

273. *b. The appearances after death by digitalis* have not been accurately observed. There is, perhaps, no drug which has been employed, either medicinally or criminally, the operation of which has been more inaccurately described than this has been. Digitalis produces but slight irritation of the digestive mucous surface, the nausea, retchings, &c., sometimes observed resulting more from the efforts of nature to throw off a depressing and poisonous agent than from any inflammatory action produced by it, these symptoms depending upon the reaction of vital organs upon an injurious influence affecting the ganglial or splanchnic nervous system rather than upon irritation. The symptoms which have been imputed to narcotism and to congestion of the brain arise from very different states; for the giddiness complained of, the convulsions even, and all the symptoms which may be referred to the brain, I am convinced, by careful observation, are results of impaired circulation in this organ, of weakened nervous energy, and of a deficiency of blood in the vessels within the head. I have always found the carotids pulsating weakly; the head cool, and the features sunk; and it is well known that convulsions as often result from a diminution of blood within the cranium as from congestion or excess—perhaps oftener. Doubtless, when convulsions occur, this state is altered, and congestion is the consequence; so that, when convulsions precede dissolution, a congested state of the vessels of the brain and of its membranes will be found. Digitalis acts as a poison, and even as a medicine, by depressing the organic or ganglial nervous energy, and consequently by lowering irritability and the tone of vascular action. The manifestations of life in the several organs are thereby similarly affected, the functions of absorption and of urinary secretion being the least disordered. The ultimate result is, that the depressed states of organic nervous power and of vascular action primarily caused by digitalis, impair the cerebro-spinal influence, and the functions of sense and of muscular motion depending upon that influence; and that these states severally act and react on each other when the poison is energetic, or its operation not counteracted, until the action of the heart ceases altogether.

274. *c. The treatment of poisoning by digitalis* must depend upon the circumstances of the case. If the symptoms are produced by a large quantity of the drug taken at once, and if there be reason to infer that it still remains even in part on the stomach, the removal of it either by the stomach-pump or by vomiting should be procured. The sulphate of zinc is the most suitable emetic in this case, and it should be given in a full emetic dose with powdered capsicum, and vomiting should be encouraged by means of warm diluents containing stimulants, as ammonia, camphor, &c. When the poison is evacuated from the stomach, or when the symptoms are consequent upon repeated doses of it, or result from its cumulative influence, an immediate recourse to stimulants, as brandy, ammonia, camphor, opium, cardiac tinctures, cap-

sicum, should be had; and mustard poultices, blisters, or other rubefacients ought to be placed over the epigastrium. Strong coffee or green tea may also be freely given. In the instances of cumulative poisoning by this plant which occurred in my practice (§ 270), camphor and ammonia, with capsicum, were chiefly employed, and green tea for drink. The noxious effects of digitalis, however produced, are not readily removed, but require the lapse of several days before they entirely disappear, the disorder of the pulse and the affection of the eyes being the last to depart. During the treatment of the effects of this poison, the patient should be kept in a recumbent position, a change to the sitting posture being allowed only with the utmost care.

275. *F. LEAD.—The preparations of lead* are severally poisonous. The metal itself is not injurious, if it remain unchanged; but when reduced to an oxide or a carbonate, it becomes injurious. Small shot have been swallowed in order to remove obstructions in the bowels, and evacuated without producing any inconvenience. Dr. BRYCE (*Lancet*, Dec. 31, 1842) has recorded a case, however, of a man who took three ounces of small shot (No. 4). On the third day he complained of great depression and anxiety, with sunken features, coldness of surface, dizziness, and numbness in the arms and legs. These symptoms continued to increase; purgations were administered to overcome the obstinate costiveness, and in a fortnight he recovered. In this case the metal was either oxydized or reduced to a salt in the stomach or intestines. The chief compounds of lead which have been found injurious are, the *carbonate*, the *acetate* and *sub-acetate*, the *chloride*, the *iodide*, and the *oxide*, combined either with vegetable acids or with fatty substances; and either of these may produce *acute* or *chronic poisoning*.

276. *a. Acetate of Lead—Sugar of Lead.*—This salt is productive of acute or chronic poisoning, according to the dose, the repetition of it, or the mode of its administration. ORFILA found that, in large doses, it caused pain, vomiting, and death; and that when its action was slower, and absorption took place, paralytic and convulsive symptoms appeared. Owing to the disposition of the salts of lead, and especially the acetate, to combine chemically with the tissues, the villous surface of the digestive canal, in cases of acute poisoning with this salt, is whitened or otherwise discoloured by it. Injected into the veins, or applied to wounds, it affects the nervous system, causing vertigo, paralysis, or coma, and convulsions, and congestion of the lungs.

277. *b. The symptoms* produced by the ingestion of this salt vary with the dose. Ten grains taken daily for seven days caused a sensation of tightness in the breast, a metallic taste of the mouth, constriction of the throat, debility, sallow countenance, slow respiration and circulation, turgid and tender gums, ptialism, numbness of the fingers and toes, pains of the stomach and bowels, costiveness, but no nausea. These symptoms are described by Dr. LAIDLAW, and agree with the symptoms I have myself observed in cases where large doses of this substance have been taken for several days. When much larger or poisonous

doses, as three or four drachms or upward, have been swallowed, a pricking, constrictive, and peculiar pain is felt in the throat and in the course of the œsophagus; pain, anxiety, and distressing aching are felt at the epigastrium, and diffusing themselves over the abdomen; vomiting takes place, and is attended by paroxysms of colicky pains, which are not increased by pressure, as in cases of inflammation, but, on the contrary, are relieved by it. Aching and anxiety, with a sensation of constriction of the abdominal contents towards the spine, are experienced in the intervals between the severe paroxysms of pain; the bowels are constipated; the skin is cold, and the strength prostrated. Giddiness, coma, convulsions, and death supervene, if suitable aid be not administered. This very *acute form* of lead poisoning is, however, comparatively rare. Much more frequently, after suffering for several days with the abdominal symptoms, the parietes of the abdomen being at first retracted, and subsequently tense and distended with air, owing to the paralyzed state of the muscular coats of the intestines, the patient complains of cramps or loss of power of the muscles of the extremities, or of numbness or complete paralysis. The bowels continue constipated; vomiting occasionally takes place, preceded or attended by severe paroxysms of pain; torpor, coma, or convulsions supervene; or death takes place suddenly or unexpectedly.

278. *c.* The effects of this salt often pursue a more *chronic* course, and then are in all respects similar to those described when treating of *painters' colic*. (See art. COLIC, § 25, *et seq.*) Dr. A. T. THOMSON (*Med. Gaz.*, vol. x., p. 689) has contended that the acetate of lead does not become poisonous until it is converted in the body into the state of a carbonate; but there is no proof of the carbonate having a more deleterious influence than the acetate. Dr. C. G. MITSCHERLICH has even shown that the acetate is not less injurious than the carbonate, especially when mixed with acetic acid, in which form it is more energetic than when given in the neutral state. (TAYLOR, *op. cit.*, p. 169)

279. *d. Sub-Acetate—Diacetate of Lead—Goulard's Extract of Lead.*—This substance has caused death in a few instances, and is a more powerful poison than the neutral salt, probably owing to its containing a larger quantity of the oxide. Mr. TAYLOR states that two cases of poisoning by GOULARD'S extract occurred in 1840 in two children of four and of six years of age. The quantity taken was not great, but both died in thirty-six hours, with symptoms very closely resembling those of pestilential cholera. The bodies were inspected (§ 285). Mr. MARSHALL, however, mentions a case of recovery from two fluid ounces of this extract.

280. *e. Carbonate of Lead—White-lead Ceruss.*—It is insoluble in water, but still possesses poisonous properties, a decided proof, as Mr. TAYLOR remarks, among numerous others, that insolubility does not prevent a substance from exerting a poisonous action on the system. The gastric and biliary secretions, or the presence of a free acid in the digestive canal, may dissolve a sufficient quantity to be deleterious. In a case reported by Dr. SNOW, a child, aged five years, ate a portion of the carbonate, ground up with oil, not larger than a marble. During

three days, pain in the abdomen and constipation alone were complained of. On the third day the symptoms were greatly aggravated, and vomiting occurred. The child died ninety hours after the injection of the poison; some very offensive stools, of a greenish-black colour, having been passed just before death. A female, aged thirty-three, took, by mistake for magnesia, from six to eight drachms of the carbonate of lead. Five hours afterward, Mr. CROSS found her in a cold perspiration, breathing heavily, with a frequent, small, constricted pulse. There were vomiting, dryness of the throat, anxious expression of countenance, and severe colicky pains. The extensor muscles became paralyzed, and the flexors rigidly contracted. Sulphate of magnesia, with dilute sulphuric acid and castor oil, were given her, and very dark evacuations were procured. In four days she was convalescent.

281. These cases sufficiently illustrate the *symptoms of the acute form* of poisoning by carbonate of lead. The *chronic form* of poisoning by this substance, characterized by severe paroxysmal pains in the bowels, constipation, paralysis, &c., is identical with *painters' colic*. (See COLIC, § 25, *et seq.*) This form of poisoning is frequently caused by the absorption of the poison either by the lungs, or by the skin, or both. It has been found that, where the carbonate of lead was ground in a dry state, both the labourers and animals have died from its effects, owing to its diffusion in a state of impalpable powder in the air. Even the air of a newly-painted room, especially when it is slept in, will, in some constitutions, produce acute or serious effects; but the chronic operation of this agent is most common. The diagnostic symptoms of this latter form of poisoning have been fully stated in the article referred to; but recently Dr. BURTON has shown, that blueness of the edges of the gums, where they join the bodies of the teeth, generally attends, or even precedes, the usual symptoms of this form. Dr. CHOWNE, however, contends that the presence or absence of this sign is not connected with the effects of lead. Chronic poisoning by the carbonate of lead is not infrequently caused by water which has passed through lead pipes, or been kept in lead cisterns, especially if these have been new, and if the water contain carbonic acid. Hard water, or water containing the sulphate of lime, or any of the neutral salts, produce little or no action on metallic lead. (See GUY'S *Hosp. Rep.*, vol. iii., p. 70.)

[As most of our large cities are supplied with water from lakes or streams conducted to reservoirs, and hence distributed, through iron or lead pipes, to the inhabitants, it becomes a question of great importance whether lead should be employed for such a purpose. The following facts are worthy of record in this connexion:

"The salt of lead formed by the contact of water with the metal is the carbonate. This salt is produced either by the action of water containing carbonic acid, or by water containing little or no saline matter. The carbonate is mixed with a small proportion of the hydrated oxide of lead. In the case of pure water, the free access of atmospheric air is essential to the change, for distilled water deprived of its gases by boiling, and excluded from the air, has no action on lead. When rain, or distilled,

or very soft water is left in contact with pure lead, with the free access of air, a white powder collects in a few minutes around the metal, and this goes on increasing till, in a few days, white, pearly scales are formed, which either float on the water, or fall to the bottom of the vessel. The formation of the carbonate and the corrosion of the metal go on as long as the air has free access to the water. At the same time a small quantity of lead is dissolved.

"On the other hand, various saline substances held in solution in water have the effect of preventing the formation of the carbonate. Indeed, all the neutral salts possess this power in a greater or less degree. Sulphate of lime affords the most complete protection, so small a quantity as one part in 5000 effectually preventing the formation of the carbonate. Some kinds of river water, as that of the Thames and the water used in Edinburgh, contain saline matters in sufficient proportion to render the use of lead perfectly safe. The same remark applies to most spring waters. But the waters of some rivers and springs are so destitute of saline matters as to act powerfully on lead.

"It may be stated, then, as a general result, that the action of water on lead, and the consequent danger of conveying and preserving it in pipes or cisterns made of that material, varies directly as the purity of the water. It follows that we may render the use of lead for such purposes perfectly safe by the artificial admixture of saline matter with the purer kinds of water. Sulphuric acid, by forming an insoluble sulphate of lead, is also an efficient protection. The use of lead is attended with most danger when it is employed to collect or preserve rain or snow water, or spring water of unusual purity, and the danger is increased by the use of leaden lids to cisterns, the pure water rising by a natural process of distillation, and collecting on the lid.

"There is one cause which greatly facilitates the action of water on lead, and which may act with sufficient energy to neutralize the preservative effects of saline matter, and be even increased by its presence, namely, the galvanic action excited by the contact of some other metal with the lead, or of the solder used for joining the sheets of lead. It must, moreover, never be forgotten that carbonic acid, if present in the water, will completely counteract the preservative effect of the salts above mentioned. We cannot, indeed, too strongly deprecate the use of lead for cisterns and water pipes under any circumstances."

The Croton water of New York contains only about four grains of solid matter to the gallon, and is consequently so pure as to act upon lead with great rapidity. The same remark will apply to the water about to be supplied to the city of Boston. Mr. EWBANK, of New York, has invented a process of tinning lead pipe, which is said to render it perfectly safe against the action of water. But it is evident that if any portion of the pipe remains untinned, galvanic action will be set up, and the lead dissolved still more rapidly. On the whole, iron pipes only should be employed for this purpose. See my appendix to *TOWERS'S Illustrations of the Croton Aqueduct*; New York and London, 1843.]

282. *f. Iodide of Lead.*—*Pulmbi Iodidum.*—As this substance is employed in medicine, it is ne-

cessary that the injurious effects produced by it should receive attention. It is a fine yellow powder, sparingly soluble in cold water, but readily soluble in boiling water. Twenty-four grains of the iodide were given to a cat, in two doses, with an interval of four hours between them. The animal suffered violent colic, and died in three days; but no signs of irritation were observed after death. Iodide of lead in doses of from five grains to thirty were given to a bulldog. On the fifteenth day the animal refused food, and kept in the recumbent posture. He died on the eighteenth day, having swallowed altogether upward of ten drachms of the iodide. During the whole period he had only three or four intestinal evacuations. I have employed this substance both internally and externally; but it has not, in the form I have prescribed it, produced any marked signs of irritation.

283. *g. The effects of the chloride of lead and of the chromate of lead* I have not observed; but there is every reason to believe that they would be poisonous in large doses, the latter especially. The sulphate of lead has usually been considered as inert by ORFILA and others. The nitrate of lead acts in a similar manner to the acetate.

284. *h. The Oxides of Lead.*—The yellow oxide, and the brown oxide—peroxide—are but little known unless to chemists. Litharge and minium (red-lead) are much used in the arts, and have caused poisoning accidentally. Liquids used for culinary or dietetic purposes, especially if they contain a free acid, may become impregnated with oxide of lead, derived from the glaze of the vessel in which they are kept forming poisonous salts. Litharge glaze may also be dissolved by alkaline and fatty substances. All newly-glazed vessels yield traces of lead on boiling in them acetic acid or caustic potash; the oxide of lead being dissolved by the acid or alkali. Litharge was formerly much employed to remove the acidity of sour wine, and convey a sweet taste; an acetate, or some other vegetable salt of lead being in these cases formed. Many years since, a fatal epidemic colic prevailed in Paris owing to this cause. The adulteration was discovered by FOURCROY. Wine thus adulterated is known by its being blackened by hydro-sulphuret of ammonia. Cider, new rum, and sugar are sometimes the medium of conveying the salts of lead, owing to lead or its oxides being employed in certain parts of the apparatus or substances used in their manufacture. Dr. TRAIL found that, when new rum is kept in oaken casks, the tannin of the oak is slowly dissolved by the spirit, and the lead is precipitated in an insoluble form, the spirit thus becoming wholesome.

285. *i. The appearances observed after death from lead poison* have been very loosely described; and those which have merely been the results of congestion, of the coagulation of the blood in the veins and venous capillaries, with more or less discoloration from the chemical action of the poison, have been stated to have been inflammatory. Dr. MITCHELL found that, when the dose of the acetate was large, the villous surface of the stomach was chemically changed by it—softened, corroded, and reduced to a whitish colour, owing to the combination of the salt with the tissue. When

given in a small dose, the acetate was decomposed by the gastric secretions, and exerted no corrosive action on the villous surface. When this salt was reduced to a state of an albuminate and dissolved by acetic acid, death took place with great rapidity; but the stomach was not found corroded. This effect was produced by the neutral salt only, and not when the dose was small, or when the poison was combined with an acid. (TAYLOR.)—In the cases of poisoning with GOULARD'S extract mentioned above (§ 279), the villous membrane of the stomach was found by Dr. BIRD of a gray colour, but otherwise perfectly healthy. The intestines were contracted, in one instance more so than in the other. In a case of acute poisoning by this extract that terminated fatally in forty-eight hours, the villous coat of the digestive canal, from the œsophagus downward, was softened, and was said to present inflammatory appearances. The mucus on the internal surface of the canal contained much of the poison. The changes observed after death from the *chronic form* of poisoning by lead are described at another place. (*See Colic*, § 25, *et seq.*)

286. *k. The modus operandi of the preparations of lead deserves attention.* These preparations, according to their physical conditions and modes of administration, may act locally or remotely, or in both ways. Certain of them, as the neutral acetate, by combining with the tissues, may act chiefly locally, and be only slowly absorbed. Their remote action may arise from their absorption from the digestive canal, from the skin, or from the lungs. When thus absorbed, to such an amount as to affect the organic nervous and vascular systems, the following effects appear: the temperature of the body sinks, the pulse becomes smaller and slower, the capillaries are somewhat constricted, the secretions from mucous surfaces diminished, and hæmorrhages, where they exist, are checked. This sedative and constringent operation is manifested chiefly in exhaling and secreting surfaces and organs. If the poison continue to be absorbed, the nervous and muscular systems are more or less affected, and the nervous and muscular systems of organic life are the first to betray disorder; as evinced by anxiety at the epigastrium, colicky pains through the abdomen, especially in the course of the colon, spasm of the muscular coats of the bowels, impaired secretion, and constipation. As the effects proceed, pain extends to the spine and to the limbs, spasms affect the muscles, especially of the extremities, or partial loss of sensibility or of the power of motion, or of both, appears. Ultimately the palsy becomes more or less complete, or giddiness, sopor, coma, or convulsions supervene, or even death takes place preceded by either of these.

287. Thus a *sedative* and an *astringent* action, and subsequently *morbid sensibility*, followed by *spasm*, and next by *palsy*, are produced by the absorption of these poisons. These effects generally appear to a greater or less extent, *first*, in the organic or involuntary, and extend to the animal or voluntary, nervous, and muscular systems. But occasionally they are only slight in the former, although severe or even fatal in the latter; or they are most severe in, or altogether limited to, the former. There can be no doubt of these effects being produced

by the presence of the poison, in the state either of an oxide, or of a salt, or in some other form or compound, in the blood, and in the tissues. ORFILA detected lead in the urine of a female who swallowed an ounce of the acetate; TIEDEMANN and GMELIN in the blood of animals poisoned by it; Mr. TAYLOR in the milk of a cow poisoned by the carbonate; and Professor COZZI, WIBMER, and others, in the blood, muscles, and viscera, after painters' colic.

288. *l. Treatment.*—The more acute form of poisoning by any of the preparations of lead requires the exhibition of demulcents or diluents, holding in solution some sulphate—as of soda, magnesia, potash, or alumina. If vomiting does not follow the free exhibition of these, the sulphate of zinc may be given, or the stomach-pump be cautiously had recourse to, or the throat or fauces may be tickled. If the patient has been poisoned by the acetate, the carbonates should be avoided, as they would increase the activity of the poison, while the sulphates would render it inert. Albumen and casein, the albuminous principle of milk, precipitate the oxides of lead, and are, therefore, excellent antidotes when given in large quantities. The treatment should be somewhat different in cases of acute poisoning by the carbonate of lead. Mr. TAYLOR remarks, that the alkaline sulphates should not be employed as antidotes for these, since it requires long digestion at a high temperature for these salts to react on the carbonate of lead, and even then the decomposition is only partial. He suggests, therefore, the administration of an alkaline sulphate mixed with vinegar, or some weak vegetable acid, such as lemon-juice. Emetics or the stomach-pump should also be employed. Afterward the bowels ought to be duly evacuated, and oleaginous and demulcent enemata thrown up. If irritability of stomach continue, opium should be given, and the colicky and paralytic symptoms ought to be treated as advised in the article *Colic* (§ 60-68).

289. *G. HYDROCYANIC ACID AND THE CYANIDES.—Oil of bitter Almonds, &c.—Prussic acid*, since its operation has been more generally known, especially as respects its rapid and unerring effects, has been frequently employed for self-destruction, and in some instances even for murder. Death has also occurred from it, owing to accident. In 1837-8 there were twenty-seven cases of poisoning by it, nearly all of which were suicidal. This substance has been variously classed by writers on *Medical Jurisprudence*; some have viewed it as a *narcotic*, because it produces insensibility in fatal cases. Others have considered it as an *irritant* poison, because it often produces spasms or convulsions, although no evidence of irritation is furnished by it on the tissues. But spasms or convulsions attend all intense impressions on the nervous system, especially when these impressions destroy life. Others, again, believe it to be both narcotic and irritant, or *narcotico-irritant*; and, not being content with imputing to it a single property which it does not possess, assign to it two properties of which it is equally devoid; for no one becomes unconscious from it, or is spasmodically or convulsively affected by it, if, indeed, they be so affected at all, until life is departing or about to depart. As it, therefore, *annihilates* the manifestations

of life in a few seconds, and in a way in which no irritant or narcotic ever acts, however energetic, comparing its action with theirs; and as there are no other terms which convey the idea of its mode of action better than *sedative* or *paralyzing*, I am obliged to adopt them, as indicating the *privation of sensibility and all vital action*, the chief properties evinced by it, when applied in a poisonous dose to a living body, as indicating the *annihilation of life*.

290. Common hydrocyanic acid is a mixture of the pure or *anhydrous acid* with water, and sometimes with alcohol. As it is kept in shops, it varies from 1·3 to 6·5 *per cent.* of the anhydrous acid. The *two* chief forms in which it is kept are that of the London Pharmacopœia, which contains 2 *per cent.*, and that of SCHEELÉ, which contains from 4 to 5 *per cent.* of anhydrous acid.

291. *a.* The *symptoms* caused by poisonous doses of this acid vary with the mode of exhibiting it, and with the quantity up to a certain amount; but, beyond that, the effects are tolerably uniform. *Inhaling the vapour* of hydrocyanic acid produces death more rapidly than any other mode of employing this poison. Dr. PEREIRA caused the almost instantaneous death of a rabbit by applying its nose to a receiver filled with the vapour. This acid also acts rapidly when applied to an *abraded surface* or to a *wound*. SOBERNHEIM states that an apothecary at Vienna died within an hour after the entrance of the acid into a wound in the hand produced by the glass vessel in which it was contained. Even when applied to the sound skin it produces some degree of action. After applying SCHEELÉ's acid to the fingers a short time, I experienced numbness, extending considerably above the place of application, that continued for several hours, and on one occasion the whole day. Dr. CHRISTISON says that M. ROBQUET's fingers were numb for several days after their exposure for some time to the vapour of the acid. Judging from these facts, this acid cannot be viewed as devoid of influence upon the *unabraded or whole skin*.

292. *b.* On *mucous membranes* this poison acts with rapidity and certainty. Mr. NUNNELEY, whose researches into the operation of this substance have been most extensive, states, that when applied upon a mucous membrane, as the conjunctiva, the rectum, or the vagina, prussic acid acts with as great rapidity as when swallowed. A knowledge of this is of importance, as poisoning may be effected in this way, and detection of the crime would be very difficult. The action of the acid on the lungs, when air impregnated with it is breathed, is not only rapid, but certain in its effects, and is one of the easiest modes of exhibiting it, but the most difficult, after a few hours, to detect, as the odour, being so diffusible, is very soon dissipated.

293. *c.* When *swallowed*, prussic acid produces almost instantaneous effects, if the quantity be sufficient to destroy life, or if the stomach be not loaded with food, which may intercept a large portion of it, and delay its operation.\*

But the *symptoms* produced by a dose hardly or barely sufficient to cause death are different from those observed when the quantity is large, and death very rapid. The effects are more rapid and certain in young and delicate persons; in weak constitutions, and when the stomach is empty, than in the middle-aged and the robust, and when the stomach contains more or less food.—(a) A *small, poisonous dose* occasions a bitter, warm taste, which is soon followed by sensations of faintness and giddiness. The respiration becomes slow, difficult, and spasmodic, the pulse small or imperceptible; and insensibility supervenes, often with convulsions; a state resembling an epileptic paroxysm being sometimes produced. The pupils are either contracted or dilated, and the eyes staring. If the treatment about to be recommended be resorted to in this state, recovery usually takes place rapidly, vomiting often occurring.

294. (b) In a *large or rapidly fatal dose*, the phenomena are such as hardly admit of observation; death follows so quickly, and is attended by so few symptoms, excepting the cessation of sensibility, of breathing, and of the heart's action. In the case of a chemist in my vicinity who took more than an ounce of SCHEELÉ's preparation, death must have occurred in a few seconds, neither spasms nor convulsions having been observed. In a case communicated by Mr. FRENCH to Mr. TAYLOR, seven drachms of the common prussic acid were taken, and about two minutes afterward he was found lying on the floor insensible. There were no convulsions of the limbs or trunk; but a slight flickering motion was observed about the muscles of the lips. Respiration seemed to cease for some seconds; it was then renewed in fits, expiration being deep and slow. The deceased took the poison while ascending the stairs; his body was found on the landing; the bottle had rolled some distance from him; the stopper was lying in another direction. SIMON relates a case in which an ounce was taken; the symptoms were the same. The hands and feet were cold, and no pulse could be felt. The finger-nails are often of a livid colour, and the hands clinched. When the dose is large, the odour of the acid is generally exhaled from the mouth.

295. *d.* The utterance of a *scream or shriek* has been said to be indicative of poisoning by this acid; but Mr. TAYLOR states that this symptom does not occur in the human subject; and Mr. MILLS, the deputy coroner, says that his inquiries show that it does not occur. There is merely a gasping for breath, or a low moaning or sobbing noise. Mr. NUNNELEY found that the shriek or cry did not occur in more than about one half the number of cases of animals, and only in one third very loudly. When it was uttered in animals, it was of a peculiar kind, and so indicative of distress as to give an idea of consciousness on the part of the animal of impending death; it was characteristic of the poison. When the dose of prussic acid is small but still fatal in the human subject, *convulsions* have sometimes been observed; but they have not been met with when the dose has been large and death rapid. In these latter cases the symptoms have been scarcely noticed, but are probably the same as seen in the lower animals, namely, imperceptible pulse,

(\* Hydrocyanic acid never operates instantaneously, as we believe, there always elapsing a sufficient interval for it to reach the brain through the medium of absorption. This fact has been abundantly proved by the experiments of Mr. BLAKE.)

insensibility, a few deep and slow respirations, and death. Mr. NUNNELEY's experiments, as well as the history of several cases in which large quantities of this poison have been swallowed, show that death is seldom so rapid as to prevent volition and voluntary motion being exercised for a few seconds afterward; but in a few seconds death often takes place without a struggle. The most rapidly fatal case with the particulars of which I am acquainted, was that of a gentleman whom I knew, and which occurred in 1828. Above an ounce of SCHEELÉ's acid was taken. Instantly upon swallowing it, he must have repented of his act, for he hastily called out, brandy, ammonia, repeating the words, fell down, and never moved afterward. In some few instances, Mr. NUNNELEY found the action of the poison so expeditious as to prevent the slightest exhibition of voluntary motion; but in the majority of warm-blooded animals and dogs, about twenty seconds elapsed before the symptoms were manifested; thus allowing, presuming that a similar interval would occur in man, sufficient time for several acts being performed, which were supposed by many to have been doubtful, if not impossible, after the ingestion of the poison.

296 *e.* It has been supposed that this acid possesses an *accumulative property*; that after having been taken for some time, in moderate doses, without any apparent mischief, it may, without any remarkable increase of quantity, suddenly give rise to all the effects of poisoning. Mr. TAYLOR states that one case is reported which renders this opinion probable, and another has been communicated to him which tends to confirm it. Dr. LONSDALE, who has paid some attention to this matter, does not admit that prussic acid possesses this property, on account of its volatility and diffusive influence; and although I have very frequently prescribed this substance, I have not seen any proof of an accumulative influence. Mr. TAYLOR states that serious effects have followed slight alterations made in the dose; but I have never met with such. The proper test is to observe whether or no such effects follow the persistence in the use of the same dose. It is very important, practically, to determine the question.

297. *f. Post-mortem Appearances.*—In cases of suicide or accident, the vessel which contained this poison will generally be found near the body. But the person poisoned may have thrown it from him upon swallowing its contents. The body commonly exhales an odour of prussic acid for some time after death; but if it has remained exposed for some time before it is seen, and especially if it be exposed to the open air, or in a shower of rain, the odour may not be perceptible. Putrefaction is said to be accelerated after death by this poison. This appeared to have been the case in two instances which I had occasion to observe. Mr. TAYLOR doubts this effect. ORFILA states that in most sudden deaths, from whatever cause, putrefaction is, *ceteris paribus*, accelerated. Externally the body is commonly livid; the nails are blue, the hands clinched. The jaws are closed; and there is some foam about the mouth, especially when death has been preceded by convulsions. The face is bloated and tumid; the eyes prominent, shining, and glassy;

and the veins are congested with dark blood. The stomach and alimentary canal are generally in a natural state; the internal surface being sometimes red or congested, as often seen after sudden death. The lungs are generally more or less congested. The brain is usually congested, especially in the less rapidly fatal cases, and when convulsions have preceded death. The blood is sometimes found quite fluid, in others thicker or semi-coagulated. It is generally of a dark colour; but Mr. TAYLOR, quoting HELLER and METZDORFF, says that it is occasionally red, or even of a pinkish hue. Other changes noticed by writers may be viewed as accidental. Indeed, there is no organic alteration observed that can account for death from this poison. Those now stated—and they are the chief met with—are slight, and are seen in other cases of sudden death. Life is so soon destroyed by this agent as not to allow of any change beyond simple congestion taking place. In a case reported by Dr. GREGG, where an ounce of the acid was swallowed, a patch of dark-red extravasation was found under the villous coat near the pylorus. In a case recorded by Mr. POOLEY, the blood was of a very dark colour; but the lungs were not congested; in one by Mr. HICKS they were much congested; while in another by Mr. NUNNELEY they were only partially congested. In an instance reported by Mr. CRISP, the abdominal and thoracic viscera were all healthy, the blood imparting to them a purple hue. (TAYLOR.)

298. On opening the stomach the odour of prussic acid is frequently perceptible, and if the quantity taken has been large, the odour may continue for several days after death. If the inspection has been recent after a large dose, the odour is often perceived in all the cavities, and even in the blood. This odour has a distant resemblance to that of bitter almonds; but it is accompanied with a peculiar impression of acridity on the nostrils and back of the throat. But this odour—the diluted odour of bitter almonds—may be perceived by some persons, and not by others; or it may be entirely absent. It may not be present, or not perceived in a very sensible manner in the dead body, if the dose of the poison has been small; or if the patient has survived a short time after it has been taken; or if it be masked by other odours; and if the body has been dead some time, or has been exposed to the air, &c. (§ 297).

[In a case which occurred in this city this day (March 22d, 1848), where a gentleman of middle age took a large quantity of hydrocyanic acid, and died in his chair, the body presented a livid appearance. The pupils of the eyes were much dilated, and the muscles of the body very rigid. On opening the chest, the lungs were found of a dark colour and much congested with blood, and presented the appearance of liver when cut. The liver was of a dark colour, and congested. The left side of the heart was empty. The right side contained a little fluid blood. The stomach contained about a gill of dark, bloody fluid, which emitted a strong odour of prussic acid. The mucous membrane was of a dark-red colour, softened and corrugated. The intestines were of a red colour. The existence of prussic acid in the stomach was so evident that there could be no doubt it

was the cause of death. In two other cases, the odour of the acid was evident on opening the cavity of the chest, as well as the stomach.]

299. *g. Relation between the Rapidity of the Effects and the Quantity and Concentration of the Poison.*—Dr. CHRISTISON has shown, that beyond a certain dose the weak and the strong acids appear to act with equal rapidity. Experiments on animals and facts observed in the human subject, show that a dose of the poison sufficient to cause death may have this effect in as short a time as a very much larger one; that a drachm of SCHEELE'S acid may cause death as rapidly as three or four times the quantity, especially if the poison be taken on an empty stomach, and if the person be weak, or debilitated by disease. It hence follows, that if two drachms of this acid be fatal in a given time, it cannot be inferred that twice or four times the quantity will be fatal in one half or one fourth of that time. Mr. NUNNELEY states, "that, when called to a person poisoned by this acid, we cannot, merely from the length of time he has survived, or the evidence of the symptoms, determine any thing with certainty as to the degree of concentration or dilution of the acid, nor, except within wide limits, much as to the absolute quantity taken." (P. 83.) He, moreover, found that concentration does not heighten the effects of this poison, but that dilution to a moderate extent even renders them more speedy, probably from bringing the poison in contact with a larger extent of surface at the same instant. It may happen that a dose just sufficient to destroy life may fail, or be longer in producing its effects, owing to its interception by the food on a full stomach, or by other circumstances pointed out above; but a quantity sufficient to destroy life under any circumstances may have this effect with as great rapidity as three or four times that quantity. Hence there is no relation, beyond a certain amount, between the rapidity of the effects, and the quantity or concentration of this poison.

300. *h. Quantity required to destroy Life.*—Dr. GEOFFREY relates an instance of a quantity of the acid having been taken equal to twenty-seven drops of the dilute acid of the London Pharmacopœia (at two per cent.) without any effect, the dose having been gradually raised to this amount; but when the dose was raised to thirty-six drops, the patient in two minutes was seized with the usual symptoms, and nearly lost his life. The quantity of anhydrous acid swallowed in this dose was only about two thirds of a grain; but, as this substance had been taken in gradually increased doses, the probability of an accumulative effect having here resulted should be taken into consideration: a question of great practical importance, but one which is solved with difficulty. Mr. HICKS furnishes, in the case which he has reported, the *smallest dose* which has been determined with accuracy as productive of death. A healthy adult female took a dose equivalent to *nine tenths* of a grain of anhydrous prussic acid, to forty-nine drops of the dilute acid of the pharmacopœia, and to twenty-five of SCHEELE'S acid. She died in twenty minutes. In a case observed by Mr. T. TAYLOR, a stout, healthy man swallowed exactly the same quantity by mistake, remained insensible for four hours, when he vomited, and began to recover. The vomited matters had

no odour of the poison, and hence absorption of it had probably taken place. This quantity, nine tenths of a grain of anhydrous acid, or *one grain*, may therefore be viewed as sufficient to destroy human life, although a somewhat smaller dose may have this effect in certain circumstances, or a somewhat larger dose may fail of producing it in others. Mr. TAYLOR thinks that the *largest dose* from which an adult has recovered was in a case reported by Mr. NUNNELEY. The person swallowed forty minims of an acid, at  $3\frac{1}{4}$  per cent. The man was for a short time conscious, got into bed after taking it, and spoke. He felt his jaw become stiff, and then remained insensible until roused by the cold affusion. Although recovery took place in this case, still the inference just stated as to the quantity which may destroy life, remains unaffected by it.

301. *i. The period at which death takes place* differs in different cases, although the dose taken may have been the same. This may be expected from the different circumstances above shown to influence the operation of poisons. In the seven cases which occurred in Paris, from the same dose of the poison given to each at the same time, death took place after periods varying from fifteen minutes to three quarters of an hour. It is only when the dose is just sufficient to cause death that an individual survives from half an hour to one hour; but I know of no case in which the period was longer than an hour. In one instance, in which seven drachms were taken, death took place within five minutes; and in another, where an ounce was swallowed, within ten minutes. In the case referred to as that in which the smallest fatal dose was observed, death occurred in twenty minutes. When the quantity is two drachms or upward, the period of death varies from two to ten minutes.

302. But it is necessary to distinguish between the periods at which insensibility and absolute death take place; for, although death does not commonly ensue until after a few minutes, insensibility, the loss of volition and consciousness may occur in a few seconds. Dr. LONSDALE states, that a drachm of SCHEELE'S acid would affect an ordinary adult within the minute, and three or four drachms within ten or fifteen seconds. When the acid is stronger, and the quantity larger, he believes the annihilation of the sensorial functions to be immediate. Mr. TAYLOR remarks, with reference to this topic, that while, as a general rule, insensibility may supervene from a large dose in a few seconds, the individual occasionally retains a power of performing certain acts indicative of consciousness, volition, and locomotion, for a few seconds.

303. *k. Diagnosis of poisoning by Prussic Acid.*—But little is required to be said as to this topic, after what has been already advanced. The effects of this poison will be readily distinguished from those of *opium* or of other *narcotics* or *acro-narcotics*, as the coma caused by these poisons is seldom seen until after the lapse of a quarter of an hour, or twenty minutes; while insensibility from this acid, even in small doses insufficient to cause death, is very rarely delayed beyond two minutes. Besides, the patient may be roused from the narcotic influence of opium or other narcotics;

but he cannot be roused from that produced by prussic acid until he entirely recovers from it. Convulsions furnish no diagnostic evidence. In poisoning by this acid, a fatal issue always occurs within an hour, more frequently within a quarter of an hour; while poisoning by the substances referred to seldom terminates fatally before a period varying from six to twelve hours. The odour of the acid, when perceived, is also an important diagnostic proof (§ 297, 298).

304. It is of the greatest importance that the effects of this poison should not be confounded with death from *epilepsy*, *apoplexy*, or *disease of the heart*, in either of which death may take place within the period in which prussic acid proves fatal. A *post-mortem* examination will generally furnish the diagnosis, when no other evidence can be obtained, or can be depended on, especially as regards apoplexy and cardiac disease; but as respects epilepsy the proofs may be incomplete, unless the odour of prussic acid be present. It may likewise be important to determine whether the poisoning by this acid has been *suicidal* or *accidental*, especially if the life of the individual be insured. In general, the several circumstances observed in connexion with the case are such as at once explain the nature of it; but there are no means by which suicide may be more secretly perpetrated than by that now discussed. As to this topic, I must refer the reader to what has been stated by Mr. TAYLOR and Dr. CHRISTISON.

305. *l. Modus operandi.*—The local and primary operation of this poison is certainly upon the nerves of the part. This is shown by the numbness produced by it when applied even to the unabraded skin. In some experiments I made with it many years ago, it was found to impair the irritability of muscular parts, and in some instances to destroy this property altogether in those parts to which it had been applied. It also in these experiments caused dilatation of the capillaries, with congestion and stagnation of the blood in them. That the local impression made upon the nerves, more especially upon those of the cerebro-spinal system, is rapidly transmitted to the brain, medulla oblongata, and spinal cord, cannot be doubted; for the abolition of the functions of those parts of the nervous system is generally so instantaneous, especially when the stomach is empty, that it cannot be imputed altogether to absorption of the poison, although absorption undoubtedly takes place very rapidly, and destroys life: the insensibility resulting more immediately from the impression of the poison, the arrest of the heart's action, and death proceeding consecutively from the absorption of it. That this poison is absorbed is fully proved by the detection of it, by chemical agents, in the blood, and by the odour of this fluid in the cavities when they are opened, and in several viscera; thus showing that its operation on organs remote from the part to which it is applied, and the death of the individual, take place mainly through this channel; that the heart is paralyzed, and its action altogether arrested by the presence of the poison in the blood. There is, however, sufficient reason to believe that the very decided and immediate impression produced by it upon the nerves of the part to which

it is applied is rapidly propagated to the *medulla oblongata* and brain, through the medium of the nerves, before the poison reaches the nervous centres, or heart, by the medium of absorption, or through the channel of the blood; for Mr. NUNNELEY found that, "when the acid was administered by the rectum or the vagina, both hind legs of the animal were sooner affected than the anterior part of the body." (P. 76.)

306. *The cause of death*, in cases of poisoning by prussic acid, appears, after the best attention I can give the subject, and after much experience of its medicinal effects, to result as follows: 1st. The deleterious impression made by the poison upon a sufficiently large surface, or to a certain amount, being transmitted by the nerves to the *medulla oblongata* or its vicinity, causes insensibility, and, if that impression is not of overpowering or annihilating intensity, convulsions also. 2d. That the deleterious impression is less violently, or more slowly developed or extended through the ganglionic nervous system; and that, before life is destroyed by the impression made on the nervous system, absorption of it, to a greater or less amount, into the circulation takes place; and, 3d. That the presence of the poison in the blood entirely abolishes the already impaired respiratory and circulating functions by its action upon the nervous centres, and on the heart itself. The poison may thus be viewed as acting primarily upon, and through the medium of the nervous system, and consecutively, by absorption and through the channel of the circulation; the latter completing what the former mode may have failed of accomplishing.

307. *m. The chemical combinations of hydrocyanic acid* are more or less poisonous.—(a) COLLON, ROBQUET, SCHUBARTH, and MAGENDIE have demonstrated the poisonous action of the *hydrocyanate of ammonia*, and of the *hydrocyanate of potass*. A dog was killed in twenty minutes with twenty drops of the diluted acid neutralized by ammonia; and another in three hours by twenty-five drops neutralized by potash. Nevertheless, ammonia is one of the best antidotes to the action of this acid, when administered after the poison. ORFILA relates a case in which six grains of the hydrocyanate of potassa proved fatal within an hour in the human subject, when administered in an injection.

308. (b) The deleterious properties of the *ferrocyanates* or *triple prussiates* are much more doubtful than those of the former. Some experimenters with it have found that the *ferrocyanate of potass* is poisonous in large quantities; while others state that it possesses little or no deleterious property. WOLLASTON, MARCET, EMMERT, MACNEVEN, and SCHUBARTH say that a drachm, or even two drachms, of this substance may be given with impunity to man or the lower animals.

309. *c. The sulpho-cyanic acid*, a substance analogous in its nature to the ferrocyanic acid, was once supposed, like it, to be a poison of great activity; but this, Dr. CHRISTISON adds, admits of some doubt. Dr. WESTRUMB considers it more poisonous in the form of *sulphocyanate of potassa*. WIMBER reports that SOEMMERING found both this acid and the salt to be poisons of great energy; for half a drachm of concentrated sulpho-cyanic acid given to a dog occasioned immediate death, and the same

quantity of the salt killed another in one minute. These substances require farther investigation. They are certainly more energetic than they have been viewed by Dr. CHRISTISON. Dr. WESTRUMB detected this salt in the blood and in the viscera.

310. (*d*) *Cyanide of potassium* is a poisonous salt much used in electro-gilding and plating. It is a solid, sometimes a chalky-looking, at others a crystallized substance, and without odour until put into water, when it is freely dissolved, forming an alkaline solution, from which prussic acid is abundantly evolved. It is used medicinally on the Continent. Mr. MALAGUTI states that a dog was killed in a few minutes after taking less than three grains of the cyanide in solution, and that the largest dose that should be given to the human subject is five sixths of a grain. A person was killed at St. Malo by too large a quantity of it having been prescribed. Another person died at Breslau after fifteen minutes from taking a dose of a mixture containing fifteen grains of this substance. The symptoms were the same as those produced by the pure acid.

311. *n. Various vegetable substances contain hydrocyanic acid*, and are poisonous in consequence. The plants which have been found to yield hydrocyanic acid belong to the division *Drupaceæ*, of DE CANDOLLE's natural order *Rosaceæ*. They are the *bitter almond*, *cherry laurel*, *bird cherry*, *peach*, and the *mountain ash*. The poison is procured from these, according to Dr. CHRISTISON, in two forms: as an essential oil, and as a distilled water. The *distilled waters* yield hydrocyanic acid, and an essential volatile oil, which also retains much of this acid, which is peculiar, and which requires farther investigations into its constitution and effects; but I must refer the reader to Dr. PEREIRA's *Materia Medica*, where the subject is fully discussed. (See vol. ii., p. 1536.)

312. (*a*) *The volatile oil of bitter almonds*, and even the bitter almonds themselves, are poisonous, and owe this property to prussic acid, none of which, however, exists already formed in the kernel of the fruit, nor is it produced unless by the agency of water on the kernel. Even the mastication of the kernel produces the poison which destroys life. Mr. TAYLOR found that mere trituration of the almond kernel with water produced hydrocyanic acid. There are instances on record, wherein these almonds, when eaten in large quantity, have produced dangerous symptoms, and even death. The *volatile essential oil* is a most active poison; its deleterious action depending entirely upon the hydrocyanic acid which is intimately combined with it. Five pounds of the almonds are said to yield about half an ounce of the oil, and the quantity of anhydrous acid contained in it varies, according to Dr. CHRISTISON, from eight to fourteen *per cent*. It is thus at least four times as strong as the dilute prussic acid of the pharmacopœia. Sir B. BROWNE, happening to touch his tongue with a rod which had been dipped in this oil, suffered almost instantaneously an indescribable sensation at the pit of the stomach, feebleness of the limbs, and loss of power over the muscles; these effects being, however, quite transient, but sufficiently evincing the rapid propagation of the deleterious impression through the medium of the nervous system.

313. Several instances of poisoning by this oil are recorded; and some have been noticed by CHRISTISON, PEREIRA, and TAYLOR. The last of these writers adduces the following: A druggist swallowed by mistake half an ounce of "almond flavour." In half a minute he fell down in a state of syncope, his face being deadly pale, and his pulse imperceptible. After some time he rallied, and vomited some undigested food and bile strongly impregnated with the odour of bitter almonds. Delirium, with slight convulsions, came on. He then became sensible, and conversed upon his condition; but he again gradually relapsed into delirium, his eyes being prominent and brilliant. In a few minutes he again became sensible, and slowly recovered. The quantity of "almond flavour" which he had taken contained about half a drachm of essential oil. In a case which occurred to Dr. BULL of Hereford, seventeen drops of the oil destroyed the life of a woman aged forty-nine in half an hour. Mr. TAYLOR here justly remarks upon the disgraceful state of medical police and legislation in this country, in the fact of a most virulent poison being sold for the purpose of flavouring pastry and liquors; but Mr. TAYLOR cannot surely be ignorant that British legislation does not concern itself with means which either destroy or preserve human life, until public opinion or an overwhelming necessity compels attention to such matters, and then they become objects of disgusting jobbing and disgraceful traffic, the measures which they produce benefiting chiefly the subservient supporters of a political party, the members of a clique, the satellites of power, and the worshippers of mammon.

314. Even a very small dose of this oil may cause fatal effects. Mr. TAYLOR, among other interesting cases, gives the following: A girl about eight or nine years of age swallowed about a teaspoonful of "ratafia," composed of one part of the essential oil of bitter almonds and seven parts of spirit. About seven drops of the oil were taken. When seen immediately after the accident there were complete insensibility, closed eyelids, brilliant and glassy eyes, dilated pupils, quick pulsation of the carotids, no pulse at the wrist, relaxation of the muscles of the extremities, and rigid contraction of the muscles of the lower jaw. Cold affusion with stimulants, stimulating frictions, and emetics were employed. Vomiting was induced; the ejecta had a strong smell of prussic acid; and the child recovered. (SMITH, in *Lancet*, June, 1844.) In a fatal case of poisoning by this oil, no odour was perceptible about the mouth when the body was found; but upon inspection, a powerful odour of prussic acid escaped from the cavities. All the viscera were in a healthy state. (*Med. Gaz.*, April 7, 1843.) The vapour of this oil, although it may cause vertigo or stupor, is not likely to produce death unless it be inhaled for a considerable time.

315. (*b*) *Laurel water*—*Cherry laurel water*—is a very weak solution of prussic acid, containing about a quarter of a grain per cent. of the strong acid. In large doses it produces the usual effects of prussic acid. *Cherry laurel* was formerly much used for flavouring liquors and sweetmeats. Almost every part of the plant is poisonous, especially the leaves and kernels, but the pulp of the cherry is not. *Cherry laurel*

oil is a weaker poison than the oil of bitter almonds, and contains about three per cent. of the anhydrous acid. COULLON relates an instance of the death of a child from the application of the leaves to a large sore on the neck. The distilled water and the oil of this plant are poisonous when introduced into the rectum, or into the cellular tissue, or injected into a vein, and when thus employed, or when swallowed, they occasion giddiness, palsy, insensibility, convulsions, and death; thus acting in a similar manner to the pure acid.

316. (c) *Peach flowers and kernels, and the fresh young shoots of the plant*, are poisonous. COULLON adduces two fatal cases of poisoning with *peach blossom*. But the effects are different from those produced by pure hydrocyanic acid, as the peach blossom acts more as an irritant of the digestive canal, and causes, in addition to insensibility and convulsions, efforts to vomit, and violent purging. A medical man swallowed half an ounce of a liquid prepared by digesting gin on a large quantity of *peach kernels*. He became giddy, and had violent constriction of the fauces, and dimness of sight. He vomited and recovered. (TAYLOR.) There are other plants which yield a distilled water and an essential oil containing more or less prussic acid; but as these are not used, at least in this country, I shall only refer to Dr. CHRISTISON's excellent work respecting them.

[We have in this country the *Prunus Virginiana* (wild cherry), *Prunus nigra* (black cherry), and *Prunus Caroliniana*, all containing hydrocyanic acid; besides the *Amygdalus Persica*, or peach (its kernels, leaves, and flowers), *Sorbus* (mountain ash), &c.

The leaves of the wild cherry are often poisonous to animals, as calves and sheep, and birds are intoxicated by its berries. An oil may be obtained by distillation from the bark, which proves extremely destructive to animal life. Mr. PRAETER, of Philadelphia, supposes this oil, when purified, to be identical with the *hydruret of benzole* (purified oil of bitter almonds) of LIEBIG and MOHLER, and that its deleterious properties are due to prussic acid alone. Children have been known to be poisoned by eating freely of the fruit of the wild cherry. The symptoms observed have been vomiting, stupor, dilated and insensible pupil, loss of strength, small and frequent pulse, pale skin, clinched jaws, inability to speak or swallow, and cold extremities. Aqua ammonia is one of the best remedies in these cases, with mustard cataplasms to the stomach and extremities. Birds are sometimes intoxicated by this fruit, and easily caught. The bark of the black cherry has proved poisonous in several instances when infused in cider. The kernels of the peach are often distilled for the purpose of impregnating *cau de noyau*, which proves poisonous when taken in any quantity.]

317. o. *Treatment of Poisoning by Prussic Acid and its Compounds*.—(a) The remedy which is most efficacious in the treatment of the effects of these poisons is fortunately one which may generally be obtained without delay, namely, *cold water*, the *affusion of which upon the head, occiput, and nape of the neck* rouses the patient from his insensibility more rapidly than any other means. This treatment was first recommended by the author of this work in the *Lon-*

*don Medical Repository* for July, 1825. It then attracted no attention, and was not even noticed by any of his contemporary editors. Dr. HERBST, of Göttingen, however, in 1828, three years afterward, recommended the same remedy, and the recommendation was then noticed in the British medical journals. The author, however, asserted his prior claims in the ninth and tenth volumes of the *Medical Gazette*. Dr. HERBST made several experiments on animals to show the efficacy of this treatment, which has now been tested in many cases in the human subject. It is, of course, the more successful the earlier it is employed; but as long as respiration and the heart's action continue, it should be resorted to and repeated according to its effects. The presence of convulsions, or of general palsy in addition to insensibility, should not prevent the administration of it. Indeed, convulsions and spasms may furnish grounds for hopes of success from it; and in cases where the insensibility and general palsy have been extreme, the occurrence of convulsions or spasms has been indications of commencing benefit. The water should be about the temperature of spring water; should be made to fall in a full and large stream upon the head—the vertex, occiput, and neck, and be repeated at short intervals, according to its effects, and in a similar way to that advised by the author for poisoning by opium. (See *Lond. Med. Repos.*, vol. xviii., and hereafter.)

318. (b) *Ammonia* has been considered by many as the most energetic antidote. It was advised by Mr. JOHN MURRAY, and may be employed by inhalation, or in any other manner, according to the state of the case. When given internally, the strong *aqua ammonia* should be diluted with twelve parts of water. It is most advantageously employed when the patient is roused, or even partially roused, by the cold affusion; and then the *inhalation* of the vapour of ammonia, if properly managed, is more efficacious than the ingestion of the remedy, which may not be accomplished, or even attempted, when insensibility, convulsions, and spasms of the muscles of the jaws are urgent.

319. (c) *Chlorine* has also been advised as an antidote for this poison by RIAUX, BUCHNER, SIMEON, COTTEREAU, and VALETTE. ORFILA considers it the most efficacious antidote of any hitherto advised. Unfortunately, the patient may be dead before the antidote can be procured in almost every instance in which it will be required. The excellence of a remedy will avail the patient but little when it cannot be procured, or when he is no longer capable of breathing or swallowing it when it reaches him, even when it has been procured with the utmost rapidity.

320. The means, therefore, upon which confidence may be placed are the cold affusion, the inhalation of the vapour of diluted ammonia, or of chlorine, when it can be obtained in time, and the ingestion of stimulants. As this poison is usually taken with a suicidal intention, an excessively large dose is generally swallowed; and this excessive quantity often precludes success from any of the means already mentioned, or from any other. The immediate evacuation of the stomach by the stomach-pump, or the administration of a zinc emetic, conjoined with cordials and stimulants, as cap-

sium, &c., ought not to be overlooked. As this poison and its compounds cause congestion of blood within the cranium, blood-letting or cupping on the nape of the neck may prove most beneficial in some cases, where this effect appears most urgent, and the habit of body admits of this practice. But it should not be overlooked that blood-letting may accelerate the absorption of the poison; and therefore the stomach should be emptied in the first place, if it be considered that much of the poison still remains in it.

321. *H. ZINC—OXIDE OF.*—This substance is not productive of serious effects even when taken in large quantity. Owing to its insolubility, its absorption must be slow. When taken internally for a long time, it acts as a slow poison, and produces a *tabes sicca*. A gentleman, for the cure of epilepsy, took daily twenty grains of the oxide, until he had consumed 3246 grains, which must have been a course of five months' duration. At the end of this time he was pale, wasted away, almost idiotic, and the surface of an earthy hue. His tongue was thickly coated, the bowels constipated, the inferior extremities cold and oedematous, the abdomen tumid, the superior extremities cold and shrivelled, and the skin dry like parchment; and the pulse about sixty, thready, and almost imperceptible. Under the use of purgatives, a light, nutritious diet, and tonic and diuretic medicines, he rapidly recovered; but still remained subject to epileptic attacks.—(*Brit. and For. Med. Review*, July, 1838.)

322. *I. THE VAPOURS OF ETHER, [OF CHLOROFORM], AND OF ALCOHOL*, when inhaled into the lungs until they are imbibed by the blood circulating in the bronchial surface and lungs, produce a paralyzing influence upon the cerebro-spinal nervous influence, the vapours of the ethers paralyzing or altogether suppressing sensibility; and the vapour of alcohol affecting more especially voluntary motion, or both voluntary motion and sensibility.\* Owing to these effects, the consideration of these agents might have fallen under the present class; but I shall notice them more particularly under the class of *stupefying or narcotic poisons*.

323. *CLASS III. EXCITANTS—STIMULANTS—EXCITING AND EXHAUSTING POISONS.*—There are various substances which are simple excitants or stimulants, as respects either the nervous influence or vascular action, and which, when taken in moderation, are in no way injurious, unless a too frequent recourse be had to them. If, however, those be administered in excessive doses, they may produce injurious or even fatal results, owing either to excessive stimulation or to its consequences, especially exhaustion, congestion, effusion, and other changes in vital organs. Fatal effects, however, from most of the substances comprised in this class, are comparatively rare; and when they produce these effects, they operate more or less upon, or through the medium of the blood; and thereby seriously affect the functions of the brain, heart, and lungs. It is not improbable that certain

excitants may act so energetically upon the nervous system, and, through them, upon the vitality of the frame, as rapidly to exhaust or destroy the influence of these systems, and vitality in all its manifestations. An intense electric shock, or lightning, may produce this effect; and we may conceive a shock from a galvanic battery of such violence as immediately to occasion the same result. In these cases the agent acts upon and through the medium of the nervous systems, although the blood and vascular system, and the muscular structures, may manifest the chief or only lesions.

324. *i. ALCOHOL—spirits of wine, spirituous liquors*, such as *gin, whisky, brandy, rum, and arrack*, have been taken in so large quantities as to produce not merely intoxication, but even death, in a few hours. The poisonous operation of alcohol has been ably investigated by Dr. CHRISTISON. In the article *DRUNKENNESS*, I have described the slowly-developed effects and ultimate results of habitual drunkenness; and the articles *DELIRIUM TREMENS* and *Granular Degeneration of the Kidneys* are illustrations of certain other forms of slow or chronic poisoning by spirituous and other intoxicating liquors. It will be necessary for me, therefore, at this place to notice only the more acute forms of poisoning by alcohol and its compounds.

325. *A. The symptoms* of the more acute states of poisoning by alcohol are, violent excitement of the nervous functions, and of the passions or emotions; flushed face; excited vascular action, followed by giddiness; confusion of thought; various mental affections, varying with the character of the individual; delirium; dozing, passing into profound somnolency, which, after several hours, is interrupted by headache, sickness, vomiting, and terminates in a heavy or stupid headache, giddiness, or nervous exhaustion. Such is the more favourable course of severe intoxication; but a more unfavourable result may accrue, either during the stage of vascular excitement, or in the following period of congestion, the somnolency deepening into profound coma, terminating in death. Dr. CHRISTISON furnishes the following illustrations of this state of poisoning: Two brothers drank in half an hour three bottles of porter, into which twenty-four ounces of whisky had been secretly mixed by a companion in order to intoxicate them. In the course of drinking, both became confused; and fifteen minutes after finishing the last bottle one of them fell down insensible, and had no recollection of what happened for twelve hours; but he recovered. The other staggered a considerable distance for an hour, and then became quite insensible. In four hours he was comatose; the breathing stertorous and irregular; the pulse eighty, and feeble; the pupils dilated and not contractile, and deglutition impossible. He remained in this state till his death, which took place fifteen hours after this debauch.

326. In this state of acute alcoholic poisoning, an apoplectic tendency may be developed into a true *apoplectic seizure*; and the usual appearances of apoplexy be found within the cranium after death, this seizure occurring either in a simple form, or associated with paralysis, especially hemiplegia. This result takes place either during the somnolent stage—this stage passing into profound coma—or a partial re-

\* We regard the effects of ether and alcohol, when inhaled in the form of vapour at least, as exactly identical, and both occasioned chiefly by the carbon and hydrogen which enter so largely into their composition, combining with the oxygen of the blood, thus substituting carbonic acid and water for the stimulating portion (oxygen) of the vital fluid.]

covery from somnolency occurs, and apoplexy, either gradually or suddenly, appears after the effects of intoxication have nearly or altogether passed off. An individual reached his home in a state of intoxication; he became lethargic, and died in the course of twenty minutes. On examining the body, Dr. ALISON could not discover any morbid appearance, except some watery effusion in the ventricles and on the surface of the brain. The contents of the stomach had a strong smell of spirits. This case, however, presents a more rapid course than is usually observed when intoxication passes directly into coma and apoplexy. A man drank thirty-two ounces of rum in the afternoon, and was comatose most of the ensuing night. Next morning, although very drowsy, he was sensible when roused; and in the evening he was convalescent. But, two days afterward, he became delirious, and in two days more comatose and apoplectic. No other morbid appearances than congestion were found in the brain.

327. In some instances, the lethargy and insensibility caused by acute intoxication are attended by *violent convulsions*, which have presented either an hysterical or an epileptic form. I was called to a female who had drunk a large quantity of spirits in a short time. She was muscular and robust, violently convulsed, unconscious, and occasionally she uttered the most distressing screams. Recourse was had to the cold affusion on the head, the convulsions assumed more of the hysterical character, and the coma was diminished and soon ceased. In another case, also of a robust female, whom I attended with Mr. LAMBERT, convulsions of an epileptic character appeared during the insensibility caused by the ingestion of a large quantity of spirits. When I saw her the symptoms were exactly those of a violent epileptic attack, and, as in the former case, characterized by the strong smell of spirits. The convulsions continued for a long time, and then passed into violent phrenitic delirium, which was not removed for several days; but recovery, complete and lasting, followed cold affusions and copious local depletions. A medical student, after drinking four bottles of Champagne, during and after dinner, besides some other wines and liquors, became phrenitically delirious. Violent convulsions supervened and recurred at intervals, during which the phrenitic symptoms continued. I saw him about thirty hours after his debauch; the maniacal delirium, and the brief attacks of convulsions, recurred almost hourly, attended by the most intense indications of vascular determination to the brain and its membranes. The treatment about to be recommended was adopted, and he recovered.

328. *B.* A still more acute state of poisoning than the above, by alcoholic liquors, is sometimes met with. When these liquors are swallowed in large quantity, in a very short time, there is seldom much preliminary excitement. Coma occurs in a few minutes, and gradually assumes an apoplectic character. The face is livid or pale, sometimes ghastly; the breathing stertorous, and with a spirituous odour; the pupils dilated and insensible, sometimes contracted; and death often takes place in a few hours. Tetanic convulsions occasionally appear in this form, although not so frequently as

in the preceding. Instances of this rapid form of poisoning have been recorded by ORFILA, BEDINGFIELD, MARX, and others. Dr. CHRISTISON mentions an instance of a man who drank at once a bottle of whisky. He died in four hours with symptoms of pure coma.

329. The effects of alcoholic liquors are greatly heightened, and often to a fatal extent, by exposure to cold either after or during the ingestion of the poison; and intoxication and insensibility more rapidly result. This is owing not only to the sedative influence of cold, but also to the partial or complete arrest of the excretion of the spirituous vapour by the lungs and skin. Most of the accidental deaths which have occurred in this country from exposure to cold during intemperate weather have been caused by a too free use of spirituous liquors just previously to such exposure, insensibility, coma, and death supervening.

330. Numerous instances have occurred, especially in this metropolis, of various liquors containing alcohol, especially malt liquors, having been made the vehicles of other poisons, and given with the intention of robbery or murder. The poisons thus administered have been usually opium or prussic acid, especially the tincture of opium. Such cases may be recognised by the fact that the effects are of a much more severe character than could result from the quantity of alcoholic fluid which had been taken. In these cases it is often very difficult to decide whether the symptoms are caused more by the alcoholic liquor than by the poison with which it was drugged.

331. *C.* The appearances observed after fatal acute poisoning by alcohol consist chiefly of increased vascularity of the internal surface of the stomach, sometimes with ecchymoses, the villous membrane presenting either a bright red, or a dark brown, or some intermediate hue; of congestion of the brain; of an increased quantity of fluid in the ventricles and between the membranes; and sometimes of effusion of blood in the substance of the brain, or between the membranes, or of a bloody serum in the latter situation. When death takes place rapidly, a strong odour of spirits may be perceived in the contents of the stomach; and in less rapid cases this odour has been said to have been perceived in the serum effused within the cranium; but this may not be felt if some time has elapsed before the inspection has been made (See art. DRUNKENNESS, § 8.)

332. *D.* The quantity required to destroy life cannot be determined. Much depends upon the age, habits, &c., of the individual, upon the state of the stomach, and upon the treatment. Young persons, not accustomed to spirits, may be killed by a comparatively small quantity. Mr. TAYLOR adduces the following: A boy, aged seven years, swallowed three ounces of brandy; shortly afterward he was observed to stagger. He was sent to bed, and vomited violently. In about four hours he was in a profuse perspiration, and his head, face, and neck were very red. Half an hour afterward he was found insensible, strongly convulsed, and the skin cold. He died in about thirty hours. Addiction to spirituous liquors often enables the system to tolerate a large quantity without much effect. A large, powerful young man, thus addicted, in the presence of the author

swallowed for a bet a bottle of rum within half an hour. He was hardly affected by it. A full stomach previously to the ingestion of spirits also affords a greater tolerance of this poison.

333. *E.* The *period* which elapses from the ingestion of the spirits until death occurs also varies with the circumstances just mentioned. Mr. TAYLOR states that the shortest period which he has seen reported occurred in a case of a man who swallowed a bottle of gin for a wager. In a quarter of an hour afterward he became intoxicated, and soon after that insensible, and died in *half an hour*, although a large quantity of the spirit had been removed by the stomach-pump. Dr. CHOWNE adduced an instance of a boy, aged eight years, who was found insensible half an hour after having taken about half a pint of gin. The liquid drawn off his stomach seven hours afterward had no odour of gin, nor was the odour of it perceptible in his breath. He was insensible and motionless; the limbs relaxed and powerless, the face pale, and the surface cold. The pulse was quick and feeble. He died, without rallying or recovering consciousness, *sixty-seven* hours after taking the poison. On *inspection*, the brain was found healthy. There were slight effusion of serum, and distention of the veins of the pia mater. The stomach was pale. No exact *period* can be assigned for the fatal termination of the effects of this poison, this termination depending chiefly upon the absorption of the spirit into the circulation, and upon the rapidity and extent of the absorption; the quantity accumulated in the blood, especially when the kidneys, lungs, and skin do not rapidly excrete it, suppressing the cerebral functions and impairing the irritability, and ultimately arresting the action of the heart.

334. *F. Treatment.*—The contents of the stomach should be withdrawn by the stomach-pump as speedily as possible; and the cold affusion ought to be resorted to immediately, in order to remove the symptoms of intoxication, or the insensibility or coma which may have already appeared. Previously to 1822, the treatment of dangerous cases of poisoning by alcoholic liquors, as well as those by narcotics, was not understood, and was certainly far from being successful. In July of that year, cases demonstrating the good effects of the cold affusion on the head in poisoning by these agents, were published by Mr. WRAY and myself (*Lond. Med. Repos.*, vol. xviii.); and the efficacy of the practice in cases of poisoning by spirits has been vouched for by Dr. OOSTROM in an able memoir on intoxication. He states that, where the temperature of the head is steadily high, and that of the surface not much reduced, it is a safe and efficacious remedy.

[We have resorted to this treatment with the greatest success, by turning a stream of cold water upon the head from a pitcher for a considerable time; in this way vomiting will often be brought on, and the patient relieved from all symptoms of intoxication.]

335. Having removed the contents of the stomach and used the cold affusion, the liquor ammoniæ acetatis with the ammonia in excess should be freely given in camphor water. Cases are comparatively rare which admit of blood-letting or even of local depletions. In young, robust, and plethoric persons not ac-

customed to intoxication, and when the affection of the brain is of a phrenic character, then vascular depletions are often required; but they should be resorted to with caution, and their effects carefully watched. When the insensibility and coma are profound, and when they resist the cold affusion on the head, the liquor ammoniæ acetatis, with the carbonate of ammonia and camphor water, should be given; and if deglutition cannot be effected, they ought to be conveyed into the stomach by the stomach-pump, or administered in enemata. Warmth, and the promotion of a free perspiration, are always beneficial. In other respects the treatment is the same as described in the articles DRUNKENNESS, and DELIRIUM WITH TREMOUR; the more *chronic states* of poisoning by alcohol being there discussed, especially under the former of these heads.

336. ii. THE ETHERS—especially the *sulphuric*, the *nitric*, and *hydrochloric*—may occasion dangerous or fatal effects when taken in excessive quantity, or when their vapours are too long *inhaled*.—*A.* When taken into the stomach, the operation of the ethers is analogous to that of spirituous liquors. M. ORFILA performed several experiments with them on the lower animals; but as these were accompanied with placing ligatures on the œsophagus, little importance can be attached to the results. I am not acquainted with any dangerous effects which have occurred from swallowing any of these ethers; and I believe that they may be taken in larger doses than they are usually prescribed, and be productive, in certain states of disease, of much benefit.

337. *B.* The *inhalation of ether*, especially the sulphuric, has lately come into vogue for the abolition of sensibility, in order that surgical operations may be performed with comfort, and even pleasure, to the patient. But it appears doubtful to me, after witnessing several instances of the inhalation of ether, whether or not the risks contingent on it do not more than compensate for the escape from pain during an operation.\* The inhalation of ether to the extent of annihilating, even for a short period, the sensibility, must necessarily be attended by changes in the nervous system; and even in the blood, otherwise a most important function—and one presiding over and directing all our animal functions—could not be entirely subverted for a time; and it may be inferred *à priori* that congestions of the brain and medulla oblongata, congestions and inflammations of the bronchi and of the lungs, and alterations of the blood, especially as regards the red globules and fibrin, will result from the passage of so large a quantity of ether into the circulation as is usually required to produce insensibility; and I believe that these results have actually accrued already, in some instances, from the practice; and that, although matters may have

[\* As ether has been employed thus far, we believe this remark perfectly just; but it remains to be proved whether ether may not be used, like other medicinal agents, with such prudence and caution that its benefits may preponderate over its evils. Its use, as well as that of chloroform, is at least justifiable, where, in severe operations, the danger of sinking, from the shock of the operation, is greater than that from inhaling these powerful agents—presuming, of course, that they prevent the shock, which is generally conceded. In the ordinary operations of dentistry and minor surgery, they should, in our judgment, be entirely abandoned.]

proceeded favourably as respects the operation, congestive bronchitis or congestive pneumonia has nevertheless been developed by it; while the absorption of purulent matter, and the occurrence of phlebitis, after great operations, have been favoured by it, by lowering the general amount of vital resistance, by affecting the constitution of the blood, and by weakening the tone of salutary vascular reaction.

338. The attempts recently made to introduce the *inhalation of ether* into general practice for the alleviation of the *pains of parturition*, as well as for trifling operations and unimportant occasions, are fraught with some danger; and I am confident that a farther experience will prove my predictions to be correct. I may here explicitly state what the danger is, as regards the *puerperal state*; namely, the supervention of *convulsions*, of *hemorrhage*, *maniacal delirium*, *puerperal fevers*, sinking of nervous power in various ways, but especially in the form of *cardiac syncope*, and inflammations of the *respiratory organs*, or of the *brain*.

339. Instances were, a few years since, published of a druggist's maid-servant having been found dead in bed, owing to the air of her apartment having been loaded with the vapour of nitric ether by the breaking of a jar containing a large quantity of this substance. She was found lying on her side, with her arms folded across the chest, the countenance and posture composed, and her whole appearance that of a person in deep sleep. The stomach was found red internally, and the lungs were gorged. The brain was not examined. A young man was found completely insensible from breathing air loaded with sulphuric ether, and remained apoplectic for some hours. I am acquainted with an instance of similar effects having accrued, from the vapour of strong spirits having been inhaled while the person was transferring the contents of a large cask into bottles.

340. C. The *treatment of insensibility* caused by ether is not materially different from that produced by ardent spirits. The cold affusion on the head and neck is the most to be confided in, if the case be in any way alarming.

[To this should be added external revulsives, as mustard, &c., and internal stimulants in the form of ammonia, camphor, &c. Exposure to fresh air, and friction, are by no means to be neglected.]

341. iii. CAMPHOR.—There are few substances the action of which is more variable, according to the dose, the mode of exhibition, state, and constitution of the patient, &c., than camphor. Hence its operation has been differently described, and its employment in disease has not been always judicious or beneficial. Having been in the habit of prescribing it, often in large doses, in various dangerous diseases, I was induced, on two occasions, to take a considerable quantity, in order to ascertain its effects from my own sensations; and on several other occasions I have taken smaller doses. These experiments were made chiefly in 1823 and 1824, and the results were published in the *London Medical Repository* for September, 1825.

342. A. The *vapour of camphor* is injurious to insects; and when long inhaled by man, it

occasions headache, pallor of the countenance, slight irritation of the respiratory mucous surfaces, followed by slight reaction of the circulation, especially in the brain and lungs. *Locally*, on the *denuded dermis*, or on the *mucous surfaces*, it appears to impress the nerves of the part; and, after rendering the part at first pale, it increases capillary injection and redness, and develops moderate vascular reaction in it. Whether applied to the skin denuded of its cuticle, or taken into the stomach, or injected into the rectum or other mucous canals, camphor is readily *absorbed* into the circulation, and is eliminated from it chiefly by the lungs and skin, and not perceptibly by the urinary organs, although it is believed to affect those organs.

343. B. The *primary action* of camphor is exerted chiefly through the medium of the nervous system; but *consecutively*, and as it becomes *absorbed* into the circulation, its action is more fully manifested on the brain, on the heart and vascular system, and on the lungs, especially on the bronchial mucous surface, as it is eliminated by the respiratory organs from the blood. The following are the results of my experiments with this substance, above alluded to (§ 341).

344. Camphor produces effects varying with the dose, and the period which elapses from the administration of it. When taken into the stomach, triturated with oil, or divided minutely by means of mucilage, magnesia, &c., fifteen grains produce the effect of half a drachm given in the form of pills or bolus, or less minutely divided; and this latter quantity sometimes produces, especially when the stomach is empty, and taken in oil or much diffused in mucilages, &c., and in certain constitutions, very severe effects. Given, therefore, in doses of from fifteen to thirty grains, diffused in mucilage, it produces the following effects, which, as they are progressively different, may be divided into *three stages*.

345. a. In the quantity just mentioned, camphor occasions a peculiar sensation of heat and constriction in the throat, and along the œsophagus as it is swallowed, followed by a similar feeling, attended by slight anxiety, at the epigastrium and region of the stomach. The sensations of internal heat and of constriction in this situation continue for some time, and are attended by slight thirst, a more constricted and slightly accelerated pulse, and a colder state of the extremities. The surface of the body also becomes cooler, and a sense of chilliness and of coldness, greater than the actual loss of temperature, is produced; yet there is, at this time, a feeling of internal warmth and excitation, as if the energies of more remote parts were drawn towards the stomach. To these sensations are added pallor of the countenance, vertigo, pindiculation or slight rigours. The head is cool, the action of the carotids somewhat diminished, and the respiration slow or natural.

346. b. In from one to two hours, the constriction and diminished action of the surface and extremities have passed off, and replaced by more or less reaction and determination of blood to the head and periphery of the body. The pulse becomes fuller and stronger; animal heat is increased; the features are more de-

veloped, and the colour returns or is increased; the vertigo, pandiculation, chilliness, and rigours having disappeared. Shortly afterward, headache, flushed face, excited pulse, sometimes noises in the ears, various but slight affection of sight, watchfulness or slight mental excitement, or delirium and disturbed sleep, in some instances, are experienced.

347. *c.* These effects having continued a few hours, the excitement of the pulse and of the brain subsides; the heat of the skin passes into a free perspiration; the pulse becomes slower and softer, and a refreshing sleep terminates the headache and slight disturbance of the brain and organs of sense; and the nervous and muscular systems remain composed. These are the usual effects of a large dose (from fifteen to thirty grains) of this substance upon a healthy person, when it is not repeated. Where smaller quantities are taken every four, or five, or six hours, the effects constituting the second stage are chiefly manifested to an extent in proportion to the amount of the doses. When dissolved in oil or in spirits, it appears to act with greater activity, and to be more readily absorbed into the circulation, where, if the dose be large, or if the doses are repeated at short intervals, it acts energetically upon the nervous system, over-exciting the brain, and causing maniacal delirium, and even convulsions and death. It seems also to possess antiseptic properties.

348. *C.* The *smallest quantity* which has produced symptoms similar to the above, calculated by their severity to cause alarm, is *one scruple*. I have often, however, given this quantity, and repeated it a second and a third time at intervals of six and eight hours, with marked benefit, in low and malignant states of fever. When given in an enema, and in a state of minute division, it often acts with great rapidity, and sometimes with great severity. Dr. CHRISTISON adduces a case where half a drachm was thus administered, and severe nervous symptoms were produced. I have often prescribed as much as this, but never more, in an enema, for insensibility or profound coma, and either alone or with asafetida; and it has sometimes been efficacious, but never injurious. In a case of most profound and protracted coma, in which deglutition was abolished, to which I was called with Mr. KINGDON and another practitioner, this substance, administered in an enema, in a very large dose, roused the patient, and procured ultimate recovery. Mr. TAYLOR adduces a case by Dr. SIEMERLING, in which a man, aged sixty-nine years, swallowed *two drachms* for the relief of rheumatism. Three hours afterward he resembled a drunken person. He complained of burning heat in the throat and stomach, of throbbings in the head, and pains in the course of the spine; of ringings in the ears, and dazzling light before his eyes. To these succeeded subsultus tendinum, and insensibility, and profuse perspiration. This last state was, however, of short duration; and he slowly recovered.

349. Dr. WENDT mentions a case in which eight scruples were taken dissolved in spirit, the *largest dose* hitherto mentioned. Vertigo, dimness of sight, delirium, and burning pain in the stomach, but no vomiting, were the only

symptoms. The man who took this quantity was an habitual drunkard; but he recovered. I have often found that drunkards may take large quantities of this substance without producing any unpleasant symptom; and I have given it in very large doses (from ten grains to one scruple) with opium for the delirium of drunkards, with marked benefit.

350. *D.* The *appearances* occasioned by poisonous doses of camphor have not been observed in man. According to the experiments of ORFILA and SCUDERY, the mucous membranes of the stomach, duodenum, and urinary organs were inflamed, and the membranes of the brain injected. The other appearances were less constant. All the cavities had a strong smell of camphor.

351. *E. Treatment.*—When the effects of camphor are not very severe, they soon pass off. But when they become alarming, whatever of this substance may still remain in the stomach should be removed by an emetic or by the stomach-pump, and demulcents with opiates, or henbane, or poppies, and the cold affusion on the head, or the shower-bath, ought to be resorted to, if maniacal delirium supervene. If convulsions or insensibility appear, the cold affusion, injections with asafetida or ammonia, and other stimulants may be administered. If strangury occur, demulcents and emollient enemata are generally of the greatest service.

252. *iv.* CHELIDONIUM MAJUS and C. GLAUCIUM produce inflammation of parts to which they are applied; but they appear to be partially absorbed, and to act upon the nervous system, causing delirium in cases where they have been partaken of by mistake. In M. ORFILA's experiments, they occasioned remarkable congestion of the lungs, whether taken into the stomach or applied to wounds.

353. *v.* HEAT, in its various forms and appearances, may be very briefly considered under the present category, as it may become more or less rapidly injurious, or even destructive of life.—*a.* *Atmospheric heat*, or the *temperature of an apartment*, may be so high as to interfere with the respiratory functions; to impede the decarbonization of the blood; to excite, and ultimately to exhaust, the nervous energy; to change the state of the blood; and, lastly, to disorder all the excreting functions, and to arrest the vital actions. When, with a high range of temperature, the living body is exposed to a stagnant state of the air, when there is not a sufficiently rapid renewal of the atmosphere, then the noxious effects are produced with a rapidity co-ordinate with the degree of atmospheric stillness; and asphyxia is produced with proportionate celerity. But when the elevation of temperature is not so great, although still high, nor ventilation so imperfect, then the deleterious changes are less rapid, and assume a slow form, inducing various *chronic affections*, more especially of the liver, stomach, and bowels, and often also of the spleen. Fatty liver, various states of enlargement and chronic change of this organ, bilious fever, &c., are not infrequent consequences of this cause, and very frequently occur, even among the inhabitants of cold regions, who shut themselves up in close apartments, warmed by stoves, during the cold seasons.

354. It is important to remark, although the circumstance must be obvious, that the air, when raised to a high temperature by the usual means resorted to in factories—by heated air, by steam, or hot water transmitted through metal pipes to different parts of the building—readily becomes stagnant, and that due ventilation is with difficulty preserved in connexion with this mode of warming, although the great numbers of persons usually employed in these places require a more than usually rapid renewal of the air. The consequences are, that the persons there employed rapidly vitiate, or even poison the air which they breathe, independently of any deleterious miasm which may be generated by the articles, materials, apparatuses, or appliances used in these manufactories.\*

355. *b. Warm Baths, Vapour Baths, Fumigating Baths.*—Medicated baths, and various natural warm or mineral baths, although beneficial when appropriately resorted to, may nevertheless become, owing to their exciting and exhausting influence, most deleterious in various states of the system, even in health, and still more so in several diseases. What is a most successful medicine when judiciously employed, becomes either a rapid or a slow poison when it is not appropriately prescribed.

356. Heat applied to the external surface in such excess as to produce scalds or burns, especially when an extensive surface is implicated, is productive of danger or death, not so much by the extent or severity of the local injury, as by the sympathetic development of inflammation of mucous or serous surfaces and its consequences.

357. *c.* The injury produced by swallowing hot or boiling fluids is dangerous or fatal, according to the amount or seat of local lesion. When the fluid is of a temperature as high as 200° or 212°, it rarely gets lower than the upper part of the gullet, and the injury is generally limited to the pharynx, epiglottis, and larynx. Accidents sometimes occur from drinking hot or boiling water from a teapot or kettle; and Dr. M. HALL has adduced the accounts of four such which occurred to children; and in all *cynanche laryngea* was produced. Two of these cases terminated by suffocation, one was relieved by tracheotomy, but died soon afterward, and the fourth recovered after having been nearly choked. (*Trans. of Lond. Med. and Chirurg. Soc.*, vol. xii., p. 1.)

358. *vi. A.* IPEACACUANHA has been considered by some as an irritant, and by others as an acronarcotic; but, strictly speaking, it cannot be viewed as either—not as an irritant, as it does not irritate or inflame the capillaries of the surfaces to which it is applied; nor as a narcotic,

for it does not stupefy. Its impression is primarily upon the nervous organization of the part to which it is applied, and is rapidly followed by muscular contraction or reaction, when the quantity of the substance is such as to produce an impression sufficiently strong to develop this effect. The susceptibility of the influence of this substance is remarkably great in some persons—so much so as to occasion the most distressing effects. When this susceptibility is great, even the presence of a few grains of ipecacuanha in the same apartment as the person thus constituted is sufficient to produce a sense of suffocation, tightness in the chest, nausea, depression, or faintness, or other disorder, varying with the idiosyncrasy of the individual; but the most frequent affection is one resembling asthma. I have met with several persons who are thus affected by the odour of ipecacuanha, or by the impalpable powder of this substance, when any of it is inhaled; and seen two instances of most distressing suffering produced by it. It is not unusual, also, even when this susceptibility of the effluvium of the drug does not exist, to meet, in the course of medical practice, with persons upon whom very minute doses of any of the preparations of ipecacuanha produce more or less distress, especially nausea, retching, and depression.\*

359. *B. Emetia [or Emetina].*—The active principle, or alkaloid of ipecacuanha, whether taken into the stomach or applied to a wound, occasioned, in the experiments of MAGENDIE, death after some hours, preceded by vomiting and coma, the lungs and stomach being found inflamed.

360. *C. Treatment.*—It is rarely that any thing more than time is required to remove the effects of ipecacuanha; for an over-dose of it is prevented from becoming injurious by its immediate rejection from the stomach. It is chiefly when, owing to idiosyncrasy, its more distressing effects are produced, that treatment is requisite. In the cases which I have treated, an open, free, and warm air, camphor with henbane taken in demulcents, and a warm mustard poultice applied over the lower part of the sternum and the epigastrium, soon removed the disorder. When nausea, retchings, and depression occur from small doses of this substance, or when the operation of it becomes exhausting or too prolonged, then small doses of ammonia and creasote, or this latter in an aromatic and emollient draught, will afford relief.

361. CLASS IV.—EXCITING AND CONSTRICTING POISONS.—*Nervous and Muscular Excitants.*—Although numerous medicinal substances act more especially upon both the nervous and the muscular or contractile systems, yet there are comparatively few of them which act so violently upon these systems as to produce death, unless they are employed improperly in the treatment of diseases, and aggravate existing morbid conditions, by interrupting the salutary efforts of nature, and by arresting or preventing the evacuation of hurtful or contaminating matters. Several substances, while they more or less excite the nervous and contractile tis-

\* [The present mode of warming apartments by means of close and air-tight stoves is, for the same reason, highly injurious, and ought to be abandoned, and either the open grate, the Franklin stove, or fireplace substituted. In a late visit to the Massachusetts General Hospital, we were exceedingly gratified in finding cheerful fires in open fireplaces in the different wards, although the building is chiefly warmed by heated air. We were informed by Dr. WARREN that, since open fires had been introduced, erysipelas, which was formerly a frequent disease in the hospital, had entirely disappeared. Wounds, also, sooner healed, and patients recovered more speedily from accidents and other diseases; puerperal females, also, had a more rapid convalescence, and altogether the effects were in the highest degree beneficial. We trust that the same mode of ventilation will be introduced into our other hospitals, and that more attention will be paid to the subject in all our public and private buildings, especially school-houses and churches.]

\* [The late Dr. URIAH TURNER of this city, a gentleman of high nervous temperament and great genius, and who was liable to severe attacks of asthma from inhaling the smallest quantity of the odour of ipecacuanha, fell a victim to an attack of this kind, induced by swallowing a few ipecacuanha pills by mistake.]

ues, become materially or chemically combined with the parts with which they are brought into contact, more especially with mucous membranes, by which they are readily imbibed. Tannin, gallic acid, and the gallates, krameria, alum, kino, catechu, solutions of several of the mineral salts, &c., while they excite nervous and contractile parts, and thereby produce a tonic effect, are partially imbibed by, or combined with, the tissues to which they are applied; and although this latter operation is not very manifest in the living textures, it is sufficiently demonstrated in dead animal matter, which is thereby preserved from decay for longer or shorter periods. The constricting influences of these and of similar substances are displayed more upon the exhaling and secreting surfaces to which they are applied than upon remote structures and organs; but when the quantity is more considerable, or when the dose is often repeated, they are then more abundantly imbibed and absorbed into the circulation, and act more or less energetically upon the nervous centres and contractile parts. Most of these substances, however, are not poisonous unless they are taken in excessive quantities, or are employed inappropriately in certain states of disease.

362. But there are some of them which are among the most virulent poisons in nature, and are exceeded only by prussic acid in their poisonous influences. These substances act chiefly by exciting the nervous systems, the excitement being propagated to the spinal cord, and reflected thence upon the muscular system, the irritability of contractile parts being inordinately excited, and being followed by various consequences, according to the persistence or the exhaustion of the excitement, and to the parts more especially affected. These substances generally increase the sensibility, and in this respect chiefly they differ from narcotic or stupefying poisons. They do not paralyze or diminish muscular contraction, but, on the contrary, inordinately excite this function, so as frequently to become incompatible with the continuance of life, tetanic asphyxia being often the more immediate cause of death. They produce no visible change in the tissues to which they are applied, or in the alimentary canal; or, if any change is observed, it is accidental, not necessarily connected with the operation of the poison, and insufficient to account for any portion of the phenomena or symptoms they produce. They act chiefly by being absorbed, and through the medium of the circulation, upon the nervous centres, more especially upon the spinal cord; and they owe their activity to an alkaloid principle which is poisonous in an extremely small dose.

363. i. ALUM.—*Sulphate of alumina and potash* can hardly be considered as a poison, although it may prove injurious when taken in very large quantity or in various disorders. It acts as an excitant and astringent, and is absorbed into the circulation; whence it is excreted chiefly by the kidneys. Its beneficial operation in lead colic is owing to its exciting the organic nervous and muscular structures of the digestive canal. M. ORFILA has detected this substance in the stomach, liver, spleen, and urine.

364. ii. NUX VOMICA—STRYCHNIA, &c.—Several species of the genus *Strychnos*, namely, *S.*

*nux vomica*, *S. Sancti Ignatii*, or St. Ignatius's Bean, *S. Colubrina*, *S. Guianensis*, *S. Ticuté*, which yields the *Upas Ticuté*, an Indian poison, &c., are extremely active poisons, and owe their activity to an alkaloid principle which has been called *Strychnia* or *Strychnine*. This substance has an intensely bitter taste, perceptible even when one grain is dissolved in 80 lbs. of water. It is sparingly soluble in water, but more abundantly in alcohol and the volatile oils. It exhibits an alkaline action, and forms neutral and crystallizable salts with the acids. Dr. CHRISTISON killed a dog in two minutes with one sixth part of a grain injected in the form of an alcoholic solution into the chest. He has seen a wild boar killed in the same manner with a third of a grain in ten minutes. There is little doubt that half a grain introduced into a wound might kill a man in a few minutes. It acts most rapidly and energetically when a solution of it is injected into a vein.

365. A. The symptoms produced by strychnia are uniform and striking, when this substance is applied in a large, poisonous dose. The animal is at first agitated, and is soon afterward seized with startings and stiffness of the limbs, which increase until it is attacked with a fit of violent general spasm, in which the head is bent back, the spine stiffened, the limbs extended and rigid, and the respiration checked by spasm of the respiratory muscles. An interval of calm succeeds, during which the sensibility is generally more than usually acute, and the senses unimpaired; but another paroxysm soon follows, each successive attack being more severe, and the intervals shorter, or less marked, until at length the severity of the fit, and the duration of the spasm of the respiratory muscles, terminate in suffocation. Dr. CHRISTISON has observed the first symptoms of this poison in from 60 to 90 seconds after the application of it to a wound; and 45 seconds after its injection into the pleura. MM. PELLETER and CAVENTOU have seen them appear after 15 seconds, when injected into this cavity. M. BOUILLAUD says that it has no effect when applied directly to a nerve.

366. B. As to the quantity of strychnia likely to destroy life, much will depend upon the mode of application, and its administration in a dissolved or undissolved state. There is no doubt that one half, or even one third of a grain, when dissolved and injected into a vein, would be sufficient to destroy a man. Three eighths of a grain given medicinally produced violent tetanic convulsions, spasms of the extremities, trismus, opisthotonos, spasmodic contraction of the respiratory muscles, &c. Dr. PEREIRA has given the particulars of a case which favours the idea that strychnia, like digitalis, accumulates in the system, and suddenly occasions violent symptoms after the exhibition of it in small and frequently repeated doses, and which demonstrates the poisonous operation of this substance in man. A Swede, between fifty and sixty years of age, suffering from general paralysis, one side being more affected than the other, took one eighth of a grain of strychnia three times a day for some weeks, without effect. The dose was increased to one quarter of a grain thrice daily, also without effect. It was farther increased to half a grain, twice or thrice a day; and this dose was taken for some

days before the effects of this substance were manifested. The patient was found in a fit. The whole body was in a state of tetanic spasm; the trunk and limbs were extended; the shoulders thrown back; the muscles rigid and hard; the face and chest were of a purple colour; respiration had ceased, and the pulsation of the heart was very weak. Artificial respiration was imperfectly kept up by compressing the thorax; and the circulation was somewhat restored. The deep purple colour of the face went off. The man sighed, and the respiration returned; but the spasms very soon appeared with increased violence, and attacked the respiratory muscles. Respiration entirely ceased, the surface again became purple, but the circulation still went on. Artificial respiration was continued imperfectly, when the relaxation of the muscles would allow of it, but was this time ineffectual. The heart soon ceased to beat, and the purple colour of the surface was instantly replaced by the pallor of death.

367. A young man swallowed forty grains of strychnia. The symptoms commenced in a quarter of an hour. Trismus and spasm of all the muscles speedily appeared, and the whole body became as stiff as a board. The lower extremities were extended and stiff, and the soles of the feet concave. The skin became livid, the eyeballs prominent, the pupils dilated and insensible, and the patient lay in a state of universal tetanus. A remission occurred, but the symptoms soon became aggravated, and the patient died asphyxiated owing to spasm of the muscles of respiration, in about an hour and a half after taking the poison. On inspection, twenty hours after death, the body was very rigid. There was affusion in the spinal sheath [probably only the spinal fluid], and the upper part of the spinal marrow was softened; the brain was congested, but the alimentary canal was in its normal state. (*Lancet*, Jan. 27, p. 647, 1838.)

368. Mr. FRENCH informed Mr. TAYLOR that a person took a grain of strychnia at a dose. Vomiting occurred, and no ill effects were produced; but half this quantity may give rise to dangerous symptoms, when taken for the first time. When commenced with in small doses and gradually increased, the system may become gradually habituated to its influence, until a large dose is reached, when its effects may be suddenly and fatally manifested, as in the case mentioned above (§ 366).

369. The operation of *strychnia*, or of its salts, or of any of the substances which contain this poison, should not be mistaken for *tetanus*. This disease is developed much more slowly, and death takes place after a much longer time, than in cases of *acute* poisoning with any of these poisons. But if the dose be small and frequently repeated, a much less acute form of poisoning may be produced, and one which may, with great difficulty, be distinguished from *tetanus*. An attempt was made to defraud insurance offices in London, by insuring the life of a young woman very largely, and destroying her by administering strychnia in porter.

[Dr. W. C. WARNER, of Bristol, Vt., died suddenly at Montpelier, October 11, 1846, aged 39, while attending the Legislature, from taking about one fourth of a grain of strychnia. In less than five minutes he felt a constriction of

the throat and tightness of the chest, with rigidity of the muscles, on attempting to move. He complained of want of air, and requested the window to be raised. He was immediately seized with a tetanic convulsion, in which his head was drawn back, his countenance became livid, fluid matters issued from his mouth, with frequent moans; the palpebræ constantly in motion. The first paroxysm lasted some five minutes, which was succeeded by an interval of partial calm, during which it was difficult for him to articulate with distinctness. He made several efforts to vomit, by exciting the fauces with his finger: there was such constriction about the throat as to prevent swallowing. This interval lasted about five minutes, when another paroxysm succeeded, by a little starting and stiffening of the extremities, and immediately the whole body was thrown into a tetanic spasm, which lasted two or three minutes, when life was extinct, in about 14 minutes from the time of swallowing the poison. The intellect remained clear to the last.—(*Bost. Med. and Surg. Journ.*)

In one case, where we recommended strychnia endermically, one third of a grain, applied to a blistered surface, nearly proved fatal; the patient, a stout man, being thrown into violent tetanic spasms, which lasted, with intervals, for more than two hours.]

370. *C. Nux Vomica*, the *Bean of St. Ignatius*, the *Upas Tieulé*, the *Wourali poison*, and the other substances enumerated above (§ 364), owe their poisonous properties to *strychnia*. St. Ignatius's bean is said to contain nearly three times the quantity of this alkaloid found in *nux vomica*. But this last substance is most frequently employed as a poison. The symptoms produced by it are similar to those caused by strychnia, but are less severe. *Nux vomica* is usually taken in the form of powder. It has an intensely and persistent bitter taste; and generally tetanic spasms appear in from five to twenty minutes after it has been taken. The symptoms are altogether the same as have been described, and death is produced by the asphyxia consequent upon the spastic contraction of the thoracic muscles.

371. Mr. BAKER states that *nux vomica* is taken by many of the nations of Hindostan habitually, generally night and morning, beginning with an eighth part of a nut, and gradually increasing the dose to an entire nut, or about twenty grains. If it be taken immediately before or after a meal, it never occasions any ill effects; but if this precaution be neglected, spasms are apt to ensue. As this substance is taken in a state of coarse powder, and not in greater quantity than one nut, and frequently after having been half roasted, it is probable that it is only slowly acted upon by the juices of the stomach; and that the modifying influence of habit as regards it is not considerable. Mr. BAKER adds that it is thus used as a preservative from lepra and some other chronic disorders; but it is more likely that it is taken on account of its tonic and aphrodisiac properties. The habitual use of this substance proves that the cumulative influence imputed to it above does not exist. (*Trans. of Med. and Phys. Soc. of Calcutta*, vol. i., p. 140.)

372. *D. As nux vomica*, in powder, in extract, and in tincture, is an excellent remedy in several

disorders, and is frequently used medicinally, the symptoms indicating its injurious operation should be more fully described. When large doses are given, the stomach often becomes disordered, the appetite impaired, and the bowels constipated. The muscular system and the sensibility are next affected. All the senses are more than usually acute. The sensibility of the surface to cold, or to slight touch, is remarkably acute; and depression of spirits, anxiety, and a feeling of weakness and weight in the limbs are complained of. Mr. PEREIRA remarks that the limbs tremble, and slight rigidity or stiffness is felt upon motion. The patient staggers, and, when he stands, a slight tap on the ham brings on a convulsive motion, which nearly throws him down. If the medicine be persevered in, these effects increase, and the voluntary muscles are thrown into a convulsed state by very slight causes. The sudden contact of external bodies acts like an electric shock upon him, and produces a convulsive paroxysm. A deep inspiration, turning suddenly in bed, startling sounds, &c., have a similar effect. The farther use of nux vomica renders the symptoms still more intense; the fits of spasm now occurring spontaneously, and without any of these provocations. It acts upon the bladder and genital organs, and exerts an aphrodisiac effect on both sexes. The pulse, however, is but little increased in frequency, and is sometimes calm even when muscular rigidity has appeared. Preceding and accompanying these effects, great sensibility of the surface, painful formications, and acuteness of the senses are experienced. The intellectual powers are unimpaired. If the use of this substance be continued, especially in an increased dose, the symptoms are still more violent, and tetanus, tetanic asphyxia, and death succeed each other with great rapidity, as they follow large doses of *strychnia* (§ 365).

373. *a.* Dr. CHRISTISON states the smallest quantity of nux vomica likely to produce death to be three grains of the alcoholic extract; which is not so small a dose as fifteen grains of the powder, which was fatal in a case adduced by Dr. TRAIL. Thirty grains, taken in two doses, caused death; and fifty grains (equal to a quarter of a grain of *strychnia*) were fatal in an hour.

374. *b.* The period after the ingestion of the poison at which death usually occurs is generally from one to two hours, but Dr. CHRISTISON mentions a case that terminated in fifteen minutes. When this poison destroys life within a few hours, or in still shorter time, vomiting rarely occurs, and the patient dies from the tetanic asphyxia. But when death does not take place thus suddenly in a fit of spasm, the person continues to be affected for twelve, or eighteen, or twenty-four hours with similar or milder paroxysms, and may expire from exhaustion, or entirely recover. A fatal termination by exhaustion is not, however, so frequent as that by asphyxia. M. J. CLOQUET met with a case of fatal exhaustion consequent upon the violent and repeated spasms produced by this substance. The tetanic fits returned for more than twenty-four hours, the sensibility being very acute. Death did not take place until the fourth morning. (*Nouv. Journ. de Med.*, t. x., p. 157.)

375. *c.* There are several instances of recovery on record. SOBERNHEIM states that a young man took half an ounce of this powder, and experienced the usual symptoms. After the administration of emetics he recovered. Dr. BASSEDOW has recorded a similar case, recovery following the operation of emetics. Mr. BAYNHAM states that a girl swallowed half an ounce of the powder; the usual symptoms appeared, but the treatment having been prompt, they subsided in about four hours from their first appearance, and the next day she was only feeble and exhausted. He says that he has often prescribed a scruple of nux vomica three times a day without any ill effects! In this, as well as in other cases, there was neither vomiting nor purging until they were produced by the treatment. A strong dose of sulphate of zinc caused free vomiting in a few minutes. (*Lond. Med. Gaz.*, vol. iii., p. 445.)

376. *E. Appearances after Death.*—These vary with the rapidity with which death takes place, and the period after death at which the body is examined. In a case recorded by Mr. OLLIER, death took place in an hour, and the changes were slight. The stomach was almost natural, although between two and three drachms of the powder of nux vomica had been taken. The vessels of the brain were somewhat congested; the heart flaccid, empty, and pale. In a case which was rapidly fatal, detailed by M. OLLIVIER, and examined by him and ORFILA, the body was found remarkably rigid, although not less than forty hours had elapsed since death. The more depending parts of the external surfaces were purplish. Much serous effusion was found on the surface of the cerebellum, and softening of the whole cortical substance of the brain, but especially of the cerebellum; this case confirming the opinion of FLOURENS, that nux vomica acts especially on the cerebellum. The lungs were congested with black fluid blood. (*Archives Génér. de Med.*, t. viii., p. 18.) In a case mentioned by Mr. TAYLOR, a quantity of the powder was found in the stomach, to the internal surface of which it adhered tenaciously. The vessels of the brain were congested. No other changes were noticed. The spastic contraction of the muscles seems to pass into the state of cadaverous rigidity after death, without intermediate flaccidity.

377. *F. Treatment.*—The most efficacious treatment of poisoning by the substances containing strychnia is an immediate recourse to the stomach-pump, and, if this apparatus is not at hand, to the more powerful emetics. Dr. CHRISTISON remarks, that, when nux vomica in powder has been taken, it adheres tenaciously to the inner surface of the stomach, and that the means used to evacuate the stomach should therefore be assiduously continued. Emetics may not act, as in Mr. OLLIER's case, therefore they ought not to be solely confided in. If the patient be not attacked with spasms in two hours, he may be considered likely to recover. In cases of poisoning with *strychnia*, the efficacy of any treatment is very doubtful, for the quantity which is poisonous is so small, and its absorption so rapid, that means must be instantly resorted to in order to be efficacious. Dr. CHRISTISON quotes M. DONNÉ, who states that he has found iodine, bromine, and chlorine

to be antidotes for poisoning with this, as well as the other vegetable alkaloids; these substances, he says, forming, with the alkaloids, compounds which are not deleterious, and which, being in chemical union, are not readily decomposed. Animals, he states, which had taken one grain of strychnia, or two grains of veratria, did not sustain any harm, when tincture of iodine was administered immediately afterward; but the delay of ten minutes in the administration of the antidote rendered it useless. Farther evidence is required as to these antidotes. Dr. PEREIRA remarks, that probably astringents, as infusions of galls, green tea, &c., would be serviceable. To relieve the spasms, narcotics may be employed. SACS and others have recommended opium. As conia is the counterpart of strychnia, it deserves a trial. Dr. PEREIRA applied it to a wound in a rabbit affected with tetanus from the use of strychnia; the convulsions ceased, but the animal died. In the absence of conia the extract of hemlock may be tried. To relieve the symptoms consequent upon the endermic application of strychnia, acetate of morphia applied to the same part has given relief. (PEREIRA, Op. cit., p. 1306.) In a case in which I pushed strychnia so far as to occasion severe spasms, spirits of turpentine were applied with tincture of opium in the form of an embrocation along the spine, and were administered in enemata with asafoetida, and the spasms very soon disappeared.

378. iii. BRUCIA—*Brucia Antidysenterica*, or *false Angustura Bark*.—This vegetable alkaloid causes symptoms of the same kind as strychnia. According to ANDRAL, brucia is twenty-four times less powerful than strychnia; but the bark itself appears to be nearly as strong as *nux vomica*. Professor MARC took an infusion of this bark in mistake for true *Angustura*; and, although the dose was only three fourths of a wineglassful, yet he was seized with nausea, pain in the stomach, giddiness, sense of fulness in the head, ringing in the ears, stiffness of the limbs, pain on every attempt at motion, locked jaw, difficult articulation, &c. These symptoms continued two hours, and abated under the use of ether and laudanum. Dr. EMMERT states, that a boy who died from taking this poison experienced so distressing a state of sensibility in the intervals between the spasms, that he begged not to be touched, as he was thereby thrown into a paroxysm. This physician has investigated the operation of this poison, and he believes that it acts directly on the spinal cord, and not through the intervention of the brain. In his experiments division of the medulla oblongata, artificial respiration being kept up, or division of the spinal cord, did not prevent the effects of the poison from being manifested in the parts supplied with nerves below the division. The symptoms and treatment of this poison are the same as those of strychnia, and of the substances which contain it. There are few other substances which are productive of death by operating in such a manner as to bring them under the present category; but the *Cocculus Indicus* and the *Coriaria myrtifolia* appear to possess properties in many respects similar to the foregoing. [The *Rhus toxicodendron*, and some of the other species, possess

tetanic properties similar to those of strychnia and brucia.]

379. iv. COCCULUS INDICUS.—*The Berries or Fruit of the Anamirta Cocculus*.—*Cocculus Indicus* is poisonous to all animals. It acts on the cerebro-spinal nervous and muscular systems, causing tremblings, staggering, tetanic convulsions, and death. It does not appear to increase the sensibility; and the coma observed is rather the result of the exhaustion of vital influence by it, than of any narcotic property, which is only produced when the dose is large, and at an advanced period of its operation. ORFILA says, that this poison acts like camphor on the nervous system, and principally on the brain. M. GOUPIE states, that it communicates its poisonous properties to fish, which have been killed by it, and more especially to barbel. It is frequently added to malt liquors for the purpose of increasing their intoxicating powers. Its active principle has been called *Picrotoxine*. Dr. PEREIRA observes that, from accounts he received from an excise officer, the action of this poison is exerted more upon the voluntary muscles than upon the intellectual powers; and that, notwithstanding the severe prohibitory statutes against the employment of *Cocculus Indicus* in brewing, there is every reason to believe that it is extensively used; but a solution of the extract being employed, the detection of it is rendered very difficult. MORRICE, a writer on brewing, directs three pounds of *Cocculus Indicus* to be added to every ten quarters of malt. "It gives," he says, "an inebriating quality, which passes for strength of liquor, and prevents second fermentation in bottled beer, and consequently the bursting of bottles in warm climates;" pleasant information this for those who indulge in these liquors; and satisfactorily accounting for the injurious operation of them on the human frame. According to WEPFER and ORFILA, this substance in poisonous doses exhausts the irritability of the heart.

380. The treatment of poisoning by *Cocculus Indicus*, or by *picrotoxine*, consists in the prompt removal of the poison from the stomach, and in having recourse to the means advised for the effects of *nux vomica* (§ 377).

381. v. CORIARIA MYRTIFOLIA possesses properties similar to the foregoing. It is frequently found as an adulteration of senna. According to Professor MAYER, it produces violent fits of tetanus, followed by apoplectic coma. A grain injected into the jugular vein of a rabbit occasioned in about five hours a single convulsive paroxysm, which proved immediately fatal. SAUVAGES has recorded two cases of death caused by the berries. M. FÉE has adduced five cases of poisoning, owing to the adulteration of senna with this substance; and one of them proved fatal. The symptoms were violent convulsions, locked jaw, and colic. M. ROUX also published, in an interesting memoir, three cases which came under his own observation, one of which proved fatal; the symptoms being sparkling and rolling of the eyes, locked jaw, loss of voice, convulsions recurring in paroxysms of the duration of eight or ten minutes, and death after sixteen hours. Of those fatal cases the membranes of the brain, on dissection, were found congested in one, no other change being observed; the internal surface of the stomach and bowels was injected

in another; and in the third no alteration could be detected. The treatment for poisoning with this substance does not differ from that recommended for the substances containing strychnia (§ 377).

382. CLASS V.—IRRITATING AND DEPRESSING POISONS.—*Irritating and Paralyzing—Acro-Sedatives*.—Although this class of poisons is more or less allied to the third and fourth classes, and not less so the sixth and eighth, still it is distinct from all of them: 1st, in the alterations of function and structures produced by it; and, 2d, as respects the treatment required to remove these alterations. The substances ranged under this class not only affect the nerves of the part to which they are applied, but irritate them, and excite more or less of morbid action of the capillaries. In conjunction with this local action, they are more or less imbibed by the membranes, and absorbed into the circulation, thereby affecting, each with modifying influence, the vital manifestations of the systems and organs of the body. Their general operation, when administered in very large or poisonous doses, is to irritate the tissues with which they come in contact, and to depress vital power throughout the frame, or to paralyze the functions of certain organs or parts. The irritating action they exert locally is extended, especially as respects some of them, to adjoining viscera; and this action is also exerted in those excreting organs which eliminate them from the blood, although often very slightly or inappreciably. But it is rare to observe after death evidence of irritation and its consequences to such an extent as to account for the fatal issue; and therefore we are induced to infer that, although these changes may have aided in producing this result, the depressing influence exerted upon the nervous systems, and upon the vitality of the frame in general, by this class of poisons, is that to which their fatal operation is mainly due. Even in those cases in which evidence of irritation, and the changes consequent upon this condition, are the most remarkable, although death may, according to the views of some, be ascribed chiefly or altogether to those changes, still they are insufficient of themselves to account for the rapidity of this issue, especially when they are compared with the extensive disorganizations observed after the more corrosive poisons, whose action is strictly local, and which often do not cause death until after prolonged periods of suffering.

383. 1. ACONITE—*Monk's-hood*—*Aconitum napellus*.—*Aconita*—*Aconitine*—*Aconitina*.—According to the observations of Dr. FLEMING, the species *napellus*, and its varieties, are the most poisonous of the genus. The amount of numbness and tingling felt on chewing the root indicates the respective activity of the various species; the power of exciting these sensations residing in the *aconitina*, which the plant contains. The most active official preparations are the tincture and alcoholic extract; but all parts of the plant are poisonous, this property residing in the *aconitina*, the alkaloid discovered in *Aconitum napellus* by GRIEGER and HESSE. Cases of poisoning by this plant are not frequent. I have seen only one instance; but injurious effects have followed, although rarely, from a too large dose of the tincture.

The expressed juice and the official preparations are most rapidly fatal when injected into a vein, or into a recent wound. They are also injurious in smaller quantity, and with greater rapidity, when introduced into the serous cavities, or in the cellular tissue, than when taken into the stomach; and they are poisonous, also, when introduced into the mucous canals.

384. A. Applied locally, aconite produces very slight irritation of the tissues; but it often excites a sense of heat. It hardly occasions any visible change of the part. On the nerves it acts as a local sedative, especially to the nerves of sensation, occasioning numbness and tingling. The loss of sensibility is followed by impairment of muscular contractility and irritability. It does not appear, according to Dr. FLEMING's experiments, to produce dilatation of the pupil; and he states that the topical application of the poison is unaccompanied by pain, redness, or swelling, even when the physiological and remote effects are produced to the greatest extent; the peculiar sensations caused by chewing the root being unattended by any inflammatory irritation.

385. B. The remote or constitutional operation of aconite depends upon the absorption of it, as shown, 1st, by the rapidity and intensity of the remote action being in proportion to the absorbing powers of the part to which it is applied, and to the facility with which the preparation employed is capable of being absorbed; 2d, by the circumstance of no remote effects, or but slight effects, being produced when it is applied to the sound skin, although the topical action indicates that the nerves were affected by it, in the manner above stated. Being imbibed and absorbed into the circulation, it acts upon the nervous system, and more especially on the cerebro-spinal nervous system; impairing the sensibility and the functions of sense, and diminishing the power of muscular action. It seems also to impair organic nervous influence and irritability, proving a sedative of the cardiac and vascular actions, and reducing, as shown by Dr. FLEMING, the strength, volume, and frequency of the pulse more or less, according to the dose. This antiphlogistic or sedative operation of aconite has been fully evinced in various diseases for which I have prescribed it. It is of importance to determine whether or no the frequent or continued exhibition of this substance produces a cumulative action. Although I have often prescribed aconite, yet I have not had reason to believe that this action has ever occurred. Dr. FLEMING, however, states that two individuals were affected with general tremours, severe pain in the head and eyeballs, constant lachrymation, intense photophobia, heat of skin, quick pulse, and great restlessness, symptoms which were distinctly attributable to the continued use of this substance.

386. C. The symptoms produced by poisonous doses of the aconite are, a sense of warmth in the stomach, with a numbness and tingling, and feeling of distention of the tongue and lips, sometimes with slight nausea, followed by vomitings or retchings. The countenance becomes pale and sunken, and muscular power prostrated. The senses are impaired, but consciousness remains, or slight wandering delirium appears. Some persons feel as if they were dying

or sinking. The voice is whispering or lost; the respiration weak and superficial; the pulse weak or slow, small or irregular. The surface is cold, and covered with a clammy sweat. At a more advanced period the patient becomes speechless, deaf, and blind. The pupils are at first contracted; but afterward, sometimes general muscular tremors or slight convulsions supervene; the pulse, at first slow, becomes imperceptible, the coldness of the surface and extremities increases, and the patient dies from syncope. In a case in which I was consulted, petechial ecchymoses appeared on the surface of the body and on the face, and marked congestion of the brain occurred with hemiplegia, yet the patient recovered, the palsy having nearly disappeared when I saw him some years afterward. In most cases, especially when any part of the plant has been ate by mistake, heat, sense of constriction, numbness and tingling in the mouth and throat are the first symptoms complained of. Vomiting or diarrhoea is generally present, with swelling of the abdomen. A lady was poisoned by eating the root in mistake for horseradish with roast beef. She could not thus have taken much of it; but shortly afterward slight vomiting, with abdominal pains, came on, and although emetics, &c., were used, she died in three hours.

387. The symptoms may appear immediately after taking the poison or not for one or two hours, the delay being owing to the part and state of the plant taken, and to the presence of food in the stomach. Five grains of the fresh extract of aconite were given to each of three patients in the hospital at Bourdeaux. In a quarter of an hour after taking the poison, they had tremors of the muscles, a pricking sensation over the body, and severe vomiting followed. They became unconscious; and on recovering their senses they complained of confusion of sight and intense headache. The pulse was slow and irregular, the respiration short and hurried; the skin was cold and clammy. Two of the patients recovered. Dr. GROGHEGAN adduces two cases, one of which died in an hour and a quarter after eating the root, and the other in two hours. One drachm of the root has proved fatal, but it is probable that less than this would kill an adult. Dr. MALE died from the effects of not more than eighty drops of the tincture taken in ten doses, over a period of four days, the largest quantity taken at once having been ten drops.

388. *D.* The alkaloid, *aconitine*, is the most virulent poison known, exceeding even prussic acid. One fiftieth part of a grain of aconitina proved nearly fatal. Its operation and effects are altogether the same as those of aconite, only much more intense.

[A ease of poisoning by *aconitina* has recently been reported by Dr. GOLDING BIRD, of London (*Med. Gazette*), which, from its interesting nature, we present to the reader. It is the first ease of the kind, we believe, ever published, although there are several on record where the roots and leaves of the aconite have accidentally produced death. There are few agents, Dr. BIRD thinks, more likely to be employed by the secret poisoner, with greater certainty of escaping detection, than aconitina.

A gentleman of high intellectual attainments, and holding an important position in society,

swallowed intentionally about two and a half grains of *aconitina*. From collateral evidence, it appeared probable that almost immediately after having taken it, he must have fallen and struck his head a severe blow against some furniture in the room. The poison, or the blow, or both, produced violent vomiting, as the room was flooded with vomited matter. Dr. BIRD saw the patient about eight hours after taking the poison. The patient was then fearfully collapsed; the surface cold and sweating; quite pale; the heart's action scarcely perceptible; pupils sensible to light; no paralysis either of sensation or motion; intellect unimpaired. The most prominent symptom was incessant and severe vomiting of a brownish fluid. This vomiting was, however, peculiar, and perhaps hardly deserved that title, the patient being really seized with a kind of general spasm, during which he convulsively turned on his abdomen, and with an intense contraction of the abdominal muscles he jerked out, as it were, the contents of the stomach, with a loud shout, depending, apparently, on the sudden contraction of the diaphragm. These exhausting and distressing symptoms occurred every minute or two. On attempting to make him swallow any fluid, a fearful spasm of the throat took place, producing the distressing effects so well known in hydrophobia; this was not produced by the sight of water, but the convulsive movements of the body, and emptying of the stomach, were excited by abruptly touching him. He was placed in a hot bath, and afterward removed to bed, covered with blankets, and a large mustard poultice to the sorculus cordis, and an enema of turpentine administered. He remained in much the same state, the sedative effects of the *aconitina* on the heart gradually lessening, so that in the course of seven hours the pulse became perceptible, though very weak; the hydrophobic symptoms were, however, then produced by every attempt to swallow, so that none of the medicines suggested could be made use of. Enemata of beef tea, and yolk of egg, with ten drops of laudanum, were administered, with the view of affording support and quieting the patient. He passed a dreadful night of exhaustion and spasm; intellect perfect, and even vivid, so as to astonish the by-standers. By two o'clock the following day the poison had so far ceased to operate, that the patient was regarded as convalescent.

The *aconitina* must in this case probably have nearly all been discharged by vomiting, and yet most violent effects followed. Dr. BIRD seems inclined to believe that the convulsive vomiting and imperfect hydrophobia are characteristic of the effects of this poison, differing, however, from the effects of aconite root, with the exception of the sedative influence on the heart. This, however, is in accordance with a fact well known, viz., that a pure alkaloid often differs materially in its physiological action from that of the plant from which it is obtained, as in the case of the alkaloid *coniin*.]

389. *E.* Death is produced by aconite owing to the sedative influence caused by it on the nervous system, or to its paralyzing effect upon the muscles of respiration, or to the impaired irregularity of the heart, fatal syncope supervening. The death of the human subject takes place generally by syncope, which sometimes

occurs suddenly, unexpectedly, and immediately: the fatal sedative and paralyzing influence of the poison on the nervous system appearing chiefly in experiments on the lower animals, when the dose of the poison has been very large.

390. *F. The appearances on dissection* have been very imperfectly observed. Venous congestion, to a greater or less extent, has generally been found. In some instances, engorgement of the brain and membranes, with considerable sub-arachnoid effusion, has been met with. In the cases recorded by PALLAS, DEGLAND, and GEOGHEGAN, inflammatory appearances were present in the alimentary canal. The lungs were generally congested, and the blood very dark.

391. *G. The more diagnostic or characteristic phenomena* produced by this poison are numbness and tingling of the mouth and throat, or parts to which it is applied; vomiting or retching, with tumefaction of the abdomen, numbness, tinglings or tremours of the extremities, contraction of the pupils, slowness or failure of the pulse and of the heart's action, and death from this last change.

392. *H. Treatment.*—If retchings only have occurred without free vomitings, an emetic, consisting of sulphate of zinc with capsicum, or of mustard mixed in water, should be administered. If the poison have passed into the intestines, or sufficient time have elapsed for this to have taken place, warm purgatives and enemata should be resorted to. Stimulants, as warm brandy and water; camphor or annomonia, with capsicum, and small doses of opium; sinapisms or terebinthinated embrocations over the epigastrium, or along the spine; strong coffee, and frictions of the surface, are the means chiefly to be confided in.

393. *ii. ARSENIC.—Arsenious Acid.—Arsenic and its Compounds.*—Of all the varieties of death by poison, none is more important, as Dr. CHRISTISON remarks, than poisoning by arsenic. The facility with which it as well as all other poisons may be procured in this country, and the ease with which it may be secretly administered, lead to its adoption for the purpose of murder. It is fortunate, therefore, that there are few substances, and hardly any other poison, which can be detected in such minute quantities, and with so great certainty, according to the full and minute directions which will be found in the works of ORFILA, PARIS, BECK, CHRISTISON, DEVERGIE, PEREIRA, TAYLOR, GUY, and others. The compounds of arsenic met with and employed in the arts, and by which life may be destroyed either accidentally or intentionally, are, 1. The protoxide of Berzelius, or fly-powder; 2. Arsenious Acid, or white arsenic; 3. The Arsenite of Copper, or mineral green; 4. The Arsenite of Potass, or Fowler's solution; 5. The Arsenate of Potass; and, 6. The various sulphurcts, pure and impure, as Realgar, Orpiment, and King's yellow. Of these, arsenious acid, or white arsenic, is that most frequently administered as a poison. Mr. TAYLOR states, that in 1837 and 1838 there were 185 cases of poisoning by this substance in England, the greater number of which were cases of suicide and murder.

394. White arsenic possesses a very feeble acid reaction, although it combines with alkalis.

It has, in small quantity, hardly any taste, and hence the frequency and risk of its employment. It is sparingly soluble. Cold water dissolves from half to one grain to one fluid ounce of water; and boiling water allowed to cool upon the powder dissolves a little more than one grain to the ounce of water. Mr. TAYLOR states that the presence of organic matter in a liquid diminishes the soluble power of the liquid. Viscid or mucilaginous fluids, of course, suspend the finer parts of the powder of this substance. The solubility and action of arsenious acid are said to be increased by admixture with nitre. This writer states that a teaspoonful of powdered arsenic weighs about 150 grains, a table-spoonful 530 grains, and a pinch about seventeen grains.

395. *A. Symptoms.*—Arsenic, taken into the stomach, produces different forms of poisoning, according to the quantity and state of the poison, as respects admixture, &c., and to the state of the stomach and constitution of the individual, according to the various modifying circumstances already mentioned (§ 51, *ct seq.*). The forms of poisoning thus resulting are, 1st. *Acute*; 2d. *Chronic*; and the acute assumes two varieties, which have been distinguished and described by Dr. CHRISTISON.

396. *a. The acute form* of poisoning with this substance is differently characterized according as the arsenic affects more especially the alimentary canal, or the nervous system, and vital powers.—(a) When the digestive canal is more particularly attacked, signs of violent irritation are manifested along its whole course, with faintness, sickness, burning pain, and tenderness in the region of the stomach. When the poison has been taken in a state of solution, these symptoms are felt very soon after its ingestion—generally from ten to fifteen minutes; but, in other circumstances, it usually does not begin to act until half an hour after it is swallowed; and its operation is seldom delayed beyond an hour. Several cases are, however, recorded in which the action of the poison was not manifested for several hours—for three, four, five, or even seven hours. Dr. CHRISTISON thinks that it is delayed for a longer or shorter time by sleep. The sickness and pain are soon followed by retchings and vomiting, especially when drink is taken. There are also heat, dryness, and tightness in the throat and pharynx, creating an incessant desire for drink, attending and occasionally preceding the vomitings. Sometimes this affection of the throat is very slight. When it is severe, it is often attended by fits of suffocation and convulsive vomiting, and by hoarseness and difficulty of talking. The matters vomited after alimentary matters have been thrown off are yellowish or greenish, and in the more protracted cases they are streaked or mixed with blood. Soon after the appearance of the gastric symptoms, diarrhœa generally supervenes; but in some instances, instead of diarrhœa, the patient is harassed by ineffectual calls, or tenesmus. About this time the pain at the pit of the stomach is excruciating, and is likened to a fire within him. It often extends over the abdomen, which becomes tense, tender, and sometimes swollen; but occasionally drawn inward at the navel. If diarrhœa be considerable, or has continued for a short time, pain, heat, and excoriation of

the anus are complained of. In some instances, the burning pain and irritation with vascular injection appears to extend from the mouth to the anus; and there are frequently, also, observed signs of irritation of the air-passages and lungs, with shortness of breath, tightness across the lower part of the chest, and occasionally darting pains. Sometimes symptoms of pneumonia are more fully developed. The urinary organs are often affected, the patient being distressed by frequent, painful, and difficult micturition, by pain in the bladder, or swelling of the penis. Females frequently experience burning pain, swelling, or excoriation of the labia pudendæ. Occasionally the irritation is so great as to cause suppression of urine; but the disorder of the urinary organs rarely occurs unless the lower bowels are also severely irritated, and the case has been protracted for two or three days. Soon after the appearance of the first symptoms, the *pulse* becomes feeble, small, and rapid, and subsequently irregular, and hardly perceptible. The surface of the body and extremities are cold, and often covered with clammy cold sweats. The feet and hands are often livid. The features are collapsed, and expressive of extreme suffering and anxiety. The conjunctiva is often very much injected; and the eyes are red and sparkling. The tongue and mouth are parched; and aphthous appearances are sometimes observed in the throat. Convulsive motions, especially of a slight form, and consisting of tremours or twitchings, often commence in the trunk and become more general. When the diarrhœa is severe, or has continued for a short time, cramps in the legs and arms are severe and frequent. Delirium sometimes appears towards the close, and is occasionally attended by stupor. Death takes place calmly, but is sometimes preceded by convulsions. In some instances, a remission of the symptoms has been observed, particularly when life has been prolonged till the close of the second or third day. In cases such as now described, constituting the most frequent variety of the acute form, death occurs about twenty-four hours after the ingestion of the poison, and generally before the close of the third day; but, in rare instances, life may be prolonged until the fifth or sixth day.

397. (b) In the *second variety* of acute poisoning by arsenic, the signs of irritation and inflammation of the digestive canal are either slight or altogether absent; death ensuing in five, six, or seven hours, or at a period too early for the full development of inflammatory action, owing to the impression of the poison on the organic nervous system, and on the general vitality of the frame. When Sir B. Brodie injected a solution of the oxide into the stomach of a dog, the pulse was rendered slow and intermitting, and the animal became palsied in the hinder legs, lethargic, and died in convulsions. In some cases of this variety, one or two attacks of vomiting occur at the usual interval after taking the poison, but it seldom continues; extreme faintness, amounting almost to syncope, being the most uniform symptom. Pain is usually felt at the epigastrium, but it is sometimes very slight, and unattended by the other signs of inflammation. Occasionally there are oppression, stupor from depression, or slight convulsions; but the faintness and gen-

eral sinking of the vital powers are the prominent phenomena, death commonly taking place in a few hours. Even in the more protracted cases, and where life continues till the second day, extreme vital depression is the most striking feature. Dr. CHRISTISON remarks that this acute variety has been observed, 1st, when the dose of the poison was very large; 2d, when it was in small masses; and, 3d, when it was in a state of solution. The first and last of these circumstances account for the rapidity and character of the symptoms, as furnishing the conditions favourable to a general or extended impression of the substance on the villous coat of the stomach, and a rapid absorption of it into the circulation; but the second circumstance just named admits not of so ready an explanation. Cases of this variety of poisoning by arsenic are not frequent; but Dr. CHRISTISON has referred to twelve instances in illustration of it; and which sufficiently show that the most rapid cases of poisoning by arsenic are not always attended by either violent or well-marked symptoms. It should, however, be recollected that the present variety passes insensibly into the former; that many cases will present phenomena approaching more or less either of the varieties now described, or intermediate between them.

398. All the above symptoms are not present in every case of the acute form, for pain may be entirely absent, although the quantity of the poison has been very great; the greatness of the quantity, as just stated, having been supposed to have been the cause of its absence. But Mr. TAYLOR states, that a case occurred in Guy's Hospital, where only forty grains had been taken, and the patient died without complaining of pain. The symptoms of intestinal irritation are seldom wanting, or there is vomiting if there be no purging. But Mr. TAYLOR refers to a case in which there was neither vomiting nor purging. Thirst, although a most common symptom, may also be absent.

399. *b. The chronic form of poisoning by arsenic may also present two varieties or states.—*  
(a) In one the symptoms may at first be acute and inflammatory; but these may subside, with or without treatment, and signs of nervous irritation and vital depression become most prominent; or the inflammatory and the nervous symptoms may appear together, and proceed *pari passu*. The nervous affection varies in different persons. It chiefly consists of partial or incomplete palsy in some cases, or of more or less complete epilepsy in others, or of partial or irregular convulsion; or they may even resemble those of hysteria, of tetanus, or of delirium, passing into stupor. Five individuals partook of a dish poisoned with arsenic, and were seized with the usual symptoms of inflammatory irritation of the alimentary canal. One of these had an epileptic fit on the first day, which returned on the second, with frequent twitches of the muscles of the trunk, numbness in one side, and heat and tingling of the feet and hands. Another had tremours of the right arm and leg, followed by epileptic fits in the night, which returned the next fifteen days at the same hour in the evening, and afterward recurred at intervals for several months.

400. Of the *secondary* effects of this variety of arsenical poisoning, *palsy* and spasm, or *con-*

tractions of the extremities, are the most frequent. The palsy is generally partial, and often commences at the fingers or toes, and proceeds gradually upward. Dr. MURRAY (*Edin. Med. and Surg. Journ.*, vol. xviii., p. 167) has given an instructive account of this effect of arsenic. Four persons were affected about an hour after breakfast with the primary symptoms of poisoning by arsenic. But, in addition to these, the muscular debility was extreme; and in two amounted to true partial palsy. One of them lost altogether the power of the left arm. The other had great general debility, and long-continued numbness and pains of the leg. In a case of an over-dose of the arseniate of potassa, the paralytic affection consisted in the loss of sensation and of motion of the hands, and the loss of motion in the feet, with contraction of the knee-joints.

401. (b) In some instances, especially when the dose of the poison has been small and frequently repeated, instead of the acute or inflammatory symptoms at the commencement, indications of slow or chronic poisoning approach insidiously, and may be mistaken for chronic disease of the digestive organs or of the nervous system. HAHNEMANN has briefly defined *slow poisoning* by arsenic as "a gradual sinking of the powers of life, without any violent symptom—a nameless feeling of illness, failure of strength, an aversion to food and drink, and all the other enjoyments of life." This is, however, not a correct view of such cases, although it may represent a few of the most slow or chronic states produced by this poison; as with the gradual sinking of vital and of muscular power, there are generally more or less of the symptoms about to be enumerated also present: Protracted indigestion with flatulence, pain in the stomach or bowels, sometimes in the course of the colon; slight diarrhœa, or tenesmus, or both; furred tongue, with dryness, constriction of the throat, and thirst; severe attacks of flatulence, sometimes with hiccough when substances are taken into the stomach; occasionally salivation or exfoliation of the epithelium of the lips, cheeks, and throat; inflammation of the conjunctiva, with suffusion of the eyes, intolerance of light, and frequently with a dark circle surrounding the eyes; irritation of the skin, often with an eruption—the *Eczema arsenicale*—and exfoliation of the cuticle, and falling out of the hair; extreme muscular weakness, tremours, paralysis, spasms, or contractions of the limbs; sometimes convulsions, anxiety, faintness, or syncope; shortness of breathing, dry cough; palpitations on slight exertion, or upon being startled, remarkable weakness, smallness, and irregularity of the pulse; emaciation, swelling or œdema of the extremities; nervous headache, mental depression, sometimes low delirium, stupor, or even death, have supervened upon excessive or too long continued doses of arsenical preparations. I once suffered severely from dyspepsia and excessive flatulence, caused by an accidental over-dose of FOWLER'S solution; and I have met with several cases where the above symptoms—some in one case, others in another, &c.—have followed the use of these preparations. There is also some reason to believe that endocarditis and lesions of the valves of the heart have been excited by the too liberal employment of the

arsenical solution. I have at present a patient with disease of the cardiac valves, who has taken the solution in very large doses, and during several protracted courses, for lepra.

402. B. The application of arsenic to sores, ulcers, or eruptions; or to wounds, or to blistered or other surfaces deprived of its cuticle, often has produced fatal poisoning. When arsenic is thus applied, both local inflammation is excited or increased, and constitutional effects are produced by its absorption. WEPFER states that a girl, affected with psoriasis of the scalp, had it rubbed with a liniment of butter and arsenic; and was soon seized with acute pain and swelling of the whole head, fainting fits, restlessness, fever, delirium, &c. She died in six days. Similar cases are recorded by AMATUS LUSITANUS, ZITMANN, BELLOC, ROUX, BLACKADDER, and others; the arsenic having been applied to sores or ulcers. HARLES remarks, respecting the propriety of the outward application of this substance, that it may be applied with safety to abraded surfaces, to common ulcers, or to malignant sores, even when highly irritable, provided the part be not recently wounded, so as to pour out blood. This distinction is not, however, to be confided in under every circumstance; for the poison may be absorbed without being imbibed by the venous capillaries of the part.

403. When arsenic is thus applied, inflammation of the part, extending more or less, is generally produced. In some instances the local irritation is but slight, or altogether absent; but it is in others very severe. The lesions consequent upon the absorption of the poison, when thus employed, are irritation of the stomach and bowels, especially of the rectum; various affections of the nervous system, as spasms, convulsions, palsy, &c.; faintness, and vital depression. In several instances palsy has appeared in parts adjoining that to which the poison was applied. An arsenical preparation was long employed to destroy a tumour on the right side of the neck, and was followed by complete palsy of the muscles of the neck and arm of that side.\*

\* [We have known three cases of death, caused by the absorption of arsenic, from cancer plasters applied by quacks for the cure of this disease. The patients died from peritonitis and enteritis, the poison being determined to the serous surfaces, there producing the ordinary symptoms of inflammation of these organs. A case is reported by Dr. HOSACK, in the *American Medical and Philosophical Register*, vol. iii., p. 389, where palsy of the right arm and neck was occasioned by the external application of arsenic, for the purpose of removing an encysted tumour on the side of the neck. Dr. MOORE HOIT, of New York, has reported a fatal case from the absorption of arsenic applied to a tumour at the angle of the jaw. (*New York Med. and Phys. Journal*, vol. iii., p. 375. In France, the *pâte arsenicale* is used, consisting of *cinnabar*, 70 parts; *Sanguis draconis*, 22; *arsenious acid*, 8; made into a paste at the time of applying it. In England, PLUNKETT'S Ointment is used, consisting of *arsenious acid*, sulphur, and the powdered leaves of the *Ranunculus inflammatum* and *Cotula fetida*; also, DAVIDSON'S Remedy for Cancer, *arsenious acid* and powdered hemlock. In the United States, we have, among others, DAVIDSON'S Cancer Plaster, the active ingredient of which is *arsenic*; the *poke-root* is also used, in form of an extract, but arsenic is mixed with it in all cases by the cancer quacks.

A medical gentleman, during the past year, being greatly annoyed by a carious tooth, was induced, by the urgent solicitation of several of his friends, to apply to the affected part a paste, in which it was ascertained the white oxide of arsenic was one of the ingredients. Within a period of two hours, local inflammation took place so rapidly as to involve the whole of the jaw of one side. Before many hours had elapsed, though active antiphlogistic means were promptly adopted, the inflammation soon involved the fauces, throat,

404. *C. The Poison may be administered in Enemata.*—FODÉRÉ adduces the following case: A lady was under treatment for some slight disorder, but died unexpectedly after symptoms of poisoning. It was afterward discovered that her servant, after unsuccessful attempts to poison her by dissolving arsenic in her soup, had succeeded by administering it in injections. In this way, doubtless, all the effects of arsenic may be produced, and the poison be the less likely to be detected after death, this mode of poisoning requiring all the vigilance which the physician can exert.

405. *D. This Poison may be introduced into the Vagina.*—Among other instances of this mode of poisoning adduced by ANSIAULX and CHRISTISON, the following is recorded by Dr. MANGOR: A farmer near Copenhagen lost his wife under suspicious circumstances, and six weeks afterward married his maid-servant. In a few years he attempted, aided by another servant, to poison his second wife. Having failed, he introduced a mixture of arsenic and flour into the vagina after coition in the morning. The symptoms appeared about midday, and death took place next morning. The murderer married, soon after, his guilty paramour, and after a few years got rid of her in a similar manner. About three in the afternoon she was seized with shivering, and with heat and pain in the vagina; the poison having been introduced in the morning. The remembrance of her former crime excited her suspicions, and she wrung from her husband a confession. On the local symptoms, acute pain in the stomach, incessant vomiting, and delirium supervened: death took place after twenty-one hours. On dissection, grains of arsenic were found in the vagina, although frequent lotions had been used

larynx, and trachea, and he died in extreme distress, with what was recorded as laryngitis, before twenty-four hours had expired from the commencement of the fatal application.

"This powerful agent" (arsenic), says Dr. FRANCIS, "whether given internally or applied externally, is capable of destroying life with equal certainty. A valuable member of our community, the late Mr. O., fell a victim to the empirical practice of arsenic, in the form of unguent, applied to a small tumour situated between his shoulders. In this case," adds Dr. F., "I had an opportunity of testing the accuracy of Mr. BRODIE's idea of the action of the arsenious acid on the human constitution. Mr. BRODIE considers this mineral poison in its operation to produce its effects primarily on the nervous system, and that death is the result of the suspension of the functions of the heart and brain. In Mr. O.'s case this theory was verified. There was paralysis of almost every limb of the body, and every joint seemed to be greatly enlarged and tumid; the intellectual functions were nearly destroyed; he died suddenly and unexpectedly, in a manner characteristic of death by arsenical poison."—*Facts on Medical Jurisprudence, New York Med. and Phys. Journal*, vol. ii.

We have facts confirmatory of this pathology in the issue of cases in which arsenic is preposterously employed for the cure of tinea capitis.

GILMAN DAVIS, of Portland, Maine, reports a case (*Boston Med. and Surg. Journal*, vol. xxviii., p. 214) of poisoning by arsenic in a woman, who took half an ounce of arsenic, attended with severe vomiting, but no pain or thirst. She took the carb. ferri in large doses, but died the next day.

Dr. STORER, of Boston, reports several cases of poisoning, in the *Boston Medical and Surgical Journal*, vol. xxiii., p. 345-8. In one case, that of Mr. KINNEY, who was supposed to have been poisoned, there was found extensive ecchymosis of the mucous membrane of the stomach, which Dr. S. considers characteristic of poisoning by this substance, and which, with the bloody tinge of the fluid in the cavity of the peritoneum and pericardium, would serve to distinguish the case from one of cholera. In one of the other cases there was no vomiting, although emetics were given, nor any pain of any kind complained of, nor swelling of abdomen. Death ensued five hours after the poison had been swallowed, perfectly rational, and without a struggle.]

in the treatment. The labia were swollen and red, the vagina flaccid, the os uteri gangrenous; the duodenum was inflamed, the stomach natural.

406. *E. Poisoning by Arsenic may take place through the Respiratory Organs.*—This usually occurs in consequence of the accidental inhalation of arsenical vapours. OTTO TACHENIUS, a chemist of the sixteenth century, quoted by Dr. CHRISTISON, states, that he once incautiously happened to breathe the fumes of arsenic, and was surprised to find his palate impressed with a sweet, mild, grateful taste, such as he never experienced before. But in half an hour he was attacked by pain and constriction of the stomach; then with difficult breathing, general convulsions, an unspeakable sense of heat, bloody and painful micturition, and, finally, with such an acute colic as contracted his whole body for half an hour. He recovered from these alarming symptoms by taking oleaginous drinks; but during all the succeeding winter he had low hectic fever. There can be no doubt of arsenical vapour or fumes being rapidly poisonous, when inhaled in a concentrated state, or even when very diluted, if longer breathed; and then they may produce slow or chronic poisoning. The vapour may even be employed in this way with criminal intentions. Dr. CHRISTISON has quoted several writers and cases illustrative of this mode of poisoning. The following is a most instructive instance of the kind: An apothecary inhaled the fumes while subliming arsenic, and was soon after seized with frequent faintness, constriction at the præcordia, difficult breathing, constant thirst, parched tongue and throat, great restlessness, watchings, and pains in the feet. He had afterward profuse daily perspirations and palsy of the legs, and several months elapsed before he quite recovered. (See B. TIMEUS, *Case. Med.*, L. vii., c. 11; and CHRISTISON, *Op. cit.*, p. 302, for similar cases.) PARACELSUS, being one day enraged with an acquaintance, held him over an alembic in which arsenic was subliming; but the object of his temper nearly lost his life.

407. *F. Applied to the sound skin*, arsenic has either no effect, or merely a slow and slight effect, unless under certain circumstances. If the poison be simply placed in contact with the skin it seldom acts; but if it be rubbed upon the skin, especially when mixed with fatty matters, it acts chiefly locally, producing a pustular eruption or eschars; but according to REHAULT it produces no constitutional disorder. This statement, however, should not be depended upon; for there are several facts recorded that prove arsenic sometimes to have been productive of very serious local and constitutional effects when applied to the human skin, either in the state of fine powder, or in the form of ointment, liniment, or paste. In these cases, several of which are adduced by Dr. CHRISTISON, the symptoms were faintings, giddiness, pain in the stomach, vomitings, tenesmus, ardor urinæ, tremblings of the limbs, low delirium, hectic fever, debility, prolonged recovery, and falling out of the hair.

408. *G. Diagnosis.*—Poisoning by arsenic may be mistaken for the severer states of cholera, or even for a case of pestilential cholera. The propriety of deciding the question from the symptoms alone, as to whether or no poi-

poisoning has been produced by arsenic, belongs more especially to the writer on Medical Jurisprudence. This question has been ably discussed by Dr. CHRISTISON and the other writers so often referred to. But the diagnosis between poisoning by this substance and natural disease falls more especially within my province. It should be admitted that the diagnosis is often difficult; but due attention to the history of the case, especially in respect of the accession of the attack; the prickings, burning sensations, or heat, redness and constriction in the throat, and in the course of the œsophagus, especially early in the attack; the redness of the eyes; the swelling, heat, pain, and excoriation of the anus; the tenesmus, and the burning or colicky character of the abdominal pain; the ardor urinae, dysuria, and heat of the urinary passages; the increased suffering on speaking and swallowing; the consecutive eruption of pimples, or excoriations of the lips, tongue, and throat; the nature of the nervous symptoms, particularly the epileptic form of convulsions, the incomplete or partial palsy, the nervous sinking, anxiety, and muscular tremours, and the low delirium, are diagnostic of poisoning, especially by this substance, and are rarely present, even individually, in cholera, and perhaps never in such states of association as are observed after the administration of arsenic. But strict attention to the phenomena and recollection of the symptoms, as described above, will show the nature of the case with tolerable certainty; although much more precise information, as respects both the moral circumstances and the chemical investigation, will be required for the administration of justice.

409. *H. The Organic Lesions produced by the Preparations of Arsenic.*—These have been described most ably by Dr. CHRISTISON, and illustrated by reference to numerous cases, to which I must refer the reader. The changes produced by arsenic are numerous, and varied in most instances, according to the quantity administered, the state of the stomach at the time, and the period the patient lived after its ingestion. Similar changes are usually observed after poisoning by the external application of the substance to those produced by its internal administration. The most remarkable alterations are generally found when the quantity swallowed has not been very large, and when the individual has lived sufficiently long to admit of the development of inflammatory action and its more immediate consequences. When death has taken place very rapidly—in a shorter period than eight, or ten, or even twelve hours, little or no change is often observed. In these cases it may be presumed that the impression of the poison on the organic nervous system, and the action consequent upon its absorption on the heart and nervous centres, cause death before vascular reaction could supervene.—*a.* Much more frequently, however, the internal surfaces of the stomach and duodenum, often also of the œsophagus and pharynx, on the one hand, and of the intestines, more especially the rectum and colon, on the other, evince signs of inflammatory irritation and certain of its more immediate results, especially capillary injection, sometimes with small ecchymosis, or slight extravasations of blood, or softening of the villous coat, or effusion of lymph, or ulcerations. Red-

ness, with vascular injection, is seldom absent from the throat and gullet, when the patient has lived above a few hours. In the stomach the colour is often a dull or brownish red; or it is of a brighter hue, interspersed with dark striæ of altered blood. The ecchymoses and larger extravasation of blood are always of a dark hue. Ulceration rarely occurs, and chiefly in cases where death has not taken place until after the second or third day. Although inflammatory appearances may be absent in cases which have ended rapidly, yet they have been found in the stomach in several which have terminated in five, six, seven, or eight hours after the administration of the poison. Thickening, or tumefaction of the villous membrane, with more or less softening, a friable state of it, and even abrasions of minute portions, are occasionally observed. Gangrene and perforations of the stomach or intestines are never found. Changes, which have been mistaken for gangrene, have consisted chiefly of extravasations of dark blood. The ulcerations said to have been found in some instances when death has taken place a few hours after the ingestion of the poison, are very probably minute abrasions or excoriations of the villous surface. A sanguinolent fluid is sometimes found in the cavity of the stomach; and occasionally arsenic, variously altered in its appearance, is found closely adhering to the internal membrane. The colon is often much contracted and its inner surface inflamed, especially the sigmoid flexure and the cæcum. The rectum is generally much inflamed and excoriated, the latter change extending around the anus, particularly when life has continued one, two, or three days.

410. *b. The respiratory organs* sometimes are found congested, and the bronchial membrane more or less reddened. Occasionally the pleura is injected, and slight effusions of serum exist in the pleural cavities. The heart is generally flabby, and sometimes the inner surface, particularly the columnæ carneæ and valves, is more or less reddened. The blood is often fluid, and generally dark-coloured. Slight effusions of serum and congestion are occasionally found within the *cranium*. Inflammatory changes are frequently seen in the *urinary passages*, and often extending to the female sexual organs.

411. *c. The antiseptic influence* of arsenic, more especially upon those parts where this substance exerts its injurious action, or where it is brought in contact, has recently attracted attention and been fully established. It thus very frequently not only preserves these parts, more especially the alimentary canal, from putrefaction, but also the alterations which it had produced in them. It may be presumed that the amount of antiseptic effect will depend very much upon the quantity of the poison, and upon the retention of it in the body at the time of death. If much of it remain in the stomach and bowels, or become absorbed and continue either in the blood or in the several tissues and organs, an antiseptic and mummifying effect may be expected; but if the poison be discharged by vomiting and purging, and eliminated from the body before death takes place, then the putrefactive process will proceed as usual, or even with greater celerity. This effect of arsenic in arresting the progress of putrefaction seems to be the result of a chemical action exerted by

this substance upon the fluids and soft solids of the body.

412. *I. The quantity of arsenic likely to destroy life* depends upon a variety of circumstances. But *four grains*, or even *three*, may kill a child, if it be taken in solution or when the stomach is empty. Dr. CHRISTISON adduces the case of a child who died in six hours after taking four grains and a half in a state of solution; and a woman, 70 years of age, was killed by four grains. Mr. TAYLOR states that a young lady died after eating a portion of cake which could not have contained more than *four grains*, and probably less than three grains. He states that three of a party at dinner who had partaken of the port wine on the table were seized with symptoms of arsenical poisoning. The wine was found to contain about one to two grains of the poison in each fluid ounce. A lady took a quantity containing less than two grains of arsenic. In about half an hour she experienced faintness, violent vomiting, but no pain. She recovered after a few hours. A gentleman took as much as contained little more than two grains. His symptoms were similar, but more severe. If he had taken another glass of the wine, he might have been killed. Although the wine was saturated with arsenic, yet no peculiar taste was perceived. The escape of these persons was probably owing to the circumstances of the wine having been taken on a full stomach, and of its having been soon followed by violent vomiting. It is probable that from one to two grains would prove fatal to a child or to a debilitated person, and three grains to an adult. On the other hand, cases of recovery from the ingestion of large quantities are not infrequent. A person recovered after taking half an ounce, the poison having been carried off by vomiting and purging; but instances of recovery from so large a quantity are very rare, and are owing to the arsenic having been taken on a full stomach, and to its speedy evacuation.

413. *K. The period at which death takes place from arsenic* varies with the circumstances so often alluded to. Dr. BORLAND informed Mr. TAYLOR of a case in which two ounces of arsenic were taken, and death took place in less than *two hours* from syncope. There was neither pain, vomiting, nor diarrhoea. Such rapidly fatal cases are very rare. But the time at which death takes place is not strictly dependent upon the quantity of the poison taken. There are many cases reported in which death has occurred in from three to seven hours, but much more frequently it does not supervene until a period varying from twelve or eighteen hours to three days, in the acute forms of poisoning by this substance. In thirteen cases recorded by Dr. BECK, the smallest quantity taken having been one drachm, and the largest two drachms, the shortest period for death was four hours, the longest two days. In one instance, two ounces of the poison destroyed life in three hours and a half; but in another case four or five grains killed a person in four hours; so little does the rapidity of the effect depend upon the dose or quantity. When the poison has been administered in small and repeated doses, and in cases of *slow* or *chronic* poisoning, and in some instances of the external application of it, and when a partial recovery from the

first effects has occurred, a fatal issue may not take place until many days or weeks after its administration.

414. *L. The modus operandi of arsenic* has not always been rightly estimated. This substance has been generally considered as a tonic; but, judging from my experience of its action in my own person, and in the treatment of many diseases, I cannot believe that it possesses any tonic properties, but, on the contrary, that it exerts an *irritating* and *depressing influence*; its chief medicinal effects being *anti-periodic* and *alterative*, effects which result from the employment of it in very small and frequently repeated doses; an irritating and depressing, or paralyzing action, following the administration of larger doses. Its local operation is chiefly as an irritant, capillary injection, inflammation, and its immediate consequences usually occurring. But the primary impression produced by large quantities of this poison is probably sedative as respects the nervous system, both locally and generally, inasmuch as death, preceded by signs of vital depression, often takes place before inflammatory appearances are developed. That *arsenic is absorbed* into the circulation, and affects this fluid, the heart, and the nervous centres, are facts which the detection of it in the liver, spleen, kidneys, [serosity of blisters], lungs, and urine, fully proves, and which the changes in these organs farther serve to show. Even when it is applied to an abraded surface, or to parts which admit of its absorption, it has been found to affect more especially the inner surface of the stomach, duodenum, and large bowels, and it has been detected in these situations by chemical research. It appears to exert a specific influence upon the alimentary canal, irritating and inflaming it, and, at the same time, depressing the organic nervous energy. It exerts, also, a marked action on the emunctories by which it is carried out of the circulation, especially the urinary organs, the villous surface and glandular apparatus of the large bowels, the skin, and lungs; exciting, irritating, or inflaming these, according to the quantity existing in the circulating fluids.

415. *M. Treatment.*—As the poisonous operation of the preparations of arsenic is chiefly owing to the absorption of them, it is obvious that, before they can be absorbed, they must be dissolved—either dissolved when administered, or subsequently by the juices of the stomach. Therefore, no substance ought to be recommended as an *antidote* unless it possesses the property of rendering the arsenic insoluble, or of preventing its solubility; and no known compound possesses this power to any considerable extent. The *hydrated sesqui-oxide of iron* possesses this property to a certain extent. Mr. TAYLOR performed many experiments on this antidote, and obtained the following results: 1st. When arsenious acid is *dissolved* in water, and agitated with twelve or fifteen times its weight of the hydrated oxide, the poison is precipitated with it in a very insoluble form. 2d. When the poison is mixed and agitated in a state of *powder* with the oxide, there is little or no effect, the poison being only mechanically diffused through the oxide. 3d. When the poison in powder is mixed with oxide of iron, rendered alkaline by ammonia, so much appears to

combine with the iron as the quantity of alkali present will render soluble in cold water. The rest is diffused in granules through the oxide. Most of the experiments, he adds, in favour of this antidote have been performed in solutions of arsenic; and therefore the results are irrelevant, since arsenic is most frequently taken in powder, and often in very coarse powder. Recently the *acetate of the sesquioxide of iron* has been recommended as an antidote by M. DUFLOS; but Mr. TAYLOR found that, in respect of arsenic in *powder*, it is as inefficacious as the hydrated oxide, even when an alkali is added, to produce effectual precipitation; and that, with regard to the solution, the poison is more readily precipitated by the hydrated oxide than by the acetate of iron. Other antidotes have been mentioned, more especially large doses of *magnesia* and *charcoal*; but they deserve little credit, and are no farther serviceable than by involving the poison more or less, and thereby preventing its action upon, or its absorption by, the surface of the stomach: an intention which may be accomplished more completely by albumen, milk, and various other substances. The substances formerly lauded as antidotes have been shown, by the researches of RENAULT, ORFILA, and others, to be quite inefficacious; whatever of success may have followed their exhibition having been owing to the several circumstances shown above (§ 51, *et seq.*) to modify, counteract, or prevent the operation of poisons.

416. So little advantage, therefore, being likely to be derived from antidotes, our chief hopes should be placed on the immediate evacuation of the poison from the stomach, and upon the removal of the injurious effects which may have been produced. If *vomiting* has not taken place, or is insufficient, it should be promoted by an emetic of sulphate of zinc, or sulphate of copper, or by mustard taken at intervals in a wineglass of water, or by tickling the throat with a feather; or the contents of the stomach may be removed by the stomach-pump, avoiding as much as possible the introduction of fluids when the poison has been taken in a state of powder or of imperfect solution. When vomiting takes place, it may be promoted by taking albumen, milk, thick mucilaginous fluids, linseed tea, &c.; and, although the patient should not be allowed to exhaust his strength in retching, without some one of these fluids being taken for the stomach to act upon, still it should not be taken in too large a quantity at one time, in order that the stomach may contract frequently on itself, and thus expel from its surface the mucous secretion which often envelops the poison, and protects the inner surface of the organ from its action. Mr. TAYLOR advises a saponaceous liquid, made of equal parts of oil and lime-water, to be given; and Dr. PARIS a free exhibition of olive oil. When vomiting has commenced from the action of the poison, an emetic or the stomach-pump is then necessary, as this operation will proceed, when aided by the fluids just mentioned.

417. Having by these means discharged the poison from the stomach, there generally remain two formidable morbid conditions produced by it to be removed. These are inflammatory irritation and action of the alimentary canal, and nervous or vital depression, with va-

rious concomitant phenomena. This association is of the most perplexing kind, inasmuch as the means calculated to relieve the one aggravates the other. Nevertheless, if there is sufficient reason to infer that the poison is altogether evacuated, and more especially if the first impression or shock produced by the poison has passed off, the pain and vomiting having developed more or less reaction, blood-letting, general or local, or both, will be practiced with advantage; but if too early resorted to, the absorption of the poison and the vital shock may be both increased by it. Terebinthinated epithems, sinapisms, or blisters over the epigastric region, or over the greater part of the abdomen, and a free exhibition of opium by the mouth, and in starch or mucilaginous enemata, are generally most beneficial; but before opium be given, the entire evacuation of the poison should be ensured. Subsequently, and when the irritation of the bowels assumes a dysenteric character, or when tenesmus or dysuria is urgent, the opium may be conjoined with ipecacuanha, camphor, nitrate of potassa, tragacanth, &c.; and these may be administered also in enemata. The medicated warm-bath; fomentations to the perinæum and anus, preceded by the application of leeches to those parts, and a farinaceous or mucilaginous diet, are important parts of the treatment.

418. The *nervous symptoms* often accompanying the vital depression produced by the poison are most successfully treated by opium taken with small doses of camphor; by the application of terebinthinated embrocations; and by mild tonics and restoratives in small doses, and in demulcent vehicles. If palsy continue after the removal of disorder of the digestive organs, exercise in the open air, the preparations of nuxvomica, or strychnia cautiously prescribed, and external irritants are the chief means of cure. If the bowels become confined, either during the more chronic cases, or during recovery or convalescence, olive oil, taken in frequently repeated doses, and administered in enemata, is the most appropriate aperient. During convalescence, and for a long period afterward, dyspepsia, flatulence, and various states of disorder of the digestive organs often continue for a long time, and are best relieved by change of air, by travelling, and by strict attention to diet; by the adoption of a bland, farinaceous diet, avoiding spirituous liquors, and the substances pointed out as injurious in the article on INDIGESTION.

419. iii. COLCHICUM AUTUMNALE — *Meadow Saffron*.—All the parts of this plant are poisonous at such periods of the year as occasion their development or perfection, but they vary slightly in their effects. The several preparations of the plant have lately been much employed in medicine, on account of their influence in paralyzing or diminishing morbid sensibility, in removing pain, and in increasing the functions of excreting organs, especially of the digestive canal, the liver, and kidneys; its effects on these, however, being by no means certain. In large doses, it acts as an irritant of the alimentary canal; and as a sedative, often remarkably depressing vascular action and vital power. Even from small or medicinal doses, these injurious effects are manifested in some instances, and not in a few of these the vital depression is ex-

treme, and consequent upon one third or one fourth of the usually prescribed medicinal dose. I have seen on several occasions poisonous effects produced by too great temerity in the use of this medicine; and these effects were not manifested so injuriously on the digestive canal as on the nervous system and vital influence; extreme sinkings, failings of the pulse, and syncope, following its ingestion. In two instances—in one a powerful man—a single dose of only ten minims of the tincture, which I prescribed for gout, produced alarming symptoms; and a drachm, taken by a medical man contrary to my advice, produced effects from which he recovered with difficulty. In some constitutions, owing to idiosyncrasy, it acts with remarkable severity, particularly as respects the vital depression produced by it. GEIGER and HESSE discovered a principle in this plant, or alkaloid, which has been called *colchieina*, *colchicia*, or *colchicine*, and which neutralizes acids, and forms with them crystallizable salts.

420. A. The symptoms arising from poisonous doses of colchicum have been described by Messrs. FEREDAY, CHEVALLIER, DILLON, HADEN, and CHRISTISON. The corns, the seeds, the flowers, and the leaves of the plant produce nearly similar symptoms when taken in large quantities. An hour, or an hour and a half, after the ingestion of the poison, acute pain, followed by retchings, vomiting, and tenesmus or purging, or both, is experienced. The pulse soon becomes feeble, the countenance anxious, and afterward the matters vomited are dark-coloured, and the purging profuse and watery. The pulse is excessively slow or feeble, the respiration hardly perceptible or feeble, the muscular weakness extreme, and the urine suppressed, the watery portions of the blood being discharged by the bowels and stomach. The patient sinks after a period, varying with the dose and the constitutional powers, from a few hours to three or four days; but there are neither convulsions, nor insensibility, nor delirium, unless in a few instances. Mr. TAYLOR states that a burning pain is felt in the throat and œsophagus; but this is not mentioned in the details of some cases, and probably it depends much upon the state in which the poison is taken. Mr. MANN communicated to him a case in which three drachms and a half of the wine of colchicum were taken in divided doses, and caused death on the fourth day. There was no inflammation of the mucous membrane found on dissection, but simply extravasation of blood into the mucous follicles. Mr. TAYLOR states, that a man took a decoction made with a table-spoonful of the seeds and a pint and a half of water. He was seized with vomiting and purging, which were incessant until death, which took place in about thirty-six hours. The only appearance of note was, that the stomach had a violet or purple hue. A gentleman swallowed, by mistake, an ounce and a half of the wine of colchicum: he was immediately seized with severe pain and the other symptoms, and died in seven hours. In another instance, where an ounce was taken, death occurred in thirty-nine hours. Most of the cases recorded of poisoning by this substance have been detailed imperfectly and loosely. In Mr. FEREDAY's case, which has been given more fully than the others, there was no cerebral disturbance.

421. B. The chief appearances observed on dissection, were a patch of redness in the internal surface of the stomach, near the cardiac orifice, and a slight effusion of blood between the muscular and peritoneal coat of a portion of the jejunum. The omentum was turned up between the stomach and convex surface of the liver behind, and the diaphragm in front. The pleuræ were somewhat reddened, and the lungs much congested with black blood. The heart was flabby, and its structure easily broken down. The surfaces of the lungs, diaphragm, and heart were covered with ecchymosed spots. The bladder was empty. The face, neck, front of the thorax, insides of the thighs, and the integuments of the scrotum and penis, were covered with patches of purple efflorescence. (*London Med. Gaz.*, vol. x., p. 160.) In the bodies of the children mentioned by BERTH there was considerable redness of the stomach and small intestines. In GEIGER's case, inflammatory appearances were seen in the stomach and small intestines. In a case related by M. CHEVALLIER, and in another adduced in the *Edinburgh Medical Journal*, no alterations were found. (CHRISTISON, *op. cit.*, p. 792.)

422. C. Treatment.—Retchings often continue for some time, and are ineffectual; therefore still vomiting should not be expected without the aid of an emetic, which may consist of sulphate of zinc or mustard mixed in water. The stomach-pump may be employed if the patient be seen soon after the ingestion of the poison. After the evacuation of it from the stomach, it remains to counteract the injurious impression produced by it on the organic nervous system, and upon the heart and nervous centres by its absorption into the circulation; and the only means we can employ with these intentions with any hopes of success, are opium, ammonia, camphor, capsicum, and creasote, variously combined, according to circumstances. I have had very frequent recourse to the preparations of colchicum in practice, but have seldom given them in full doses without conjoining them with one or more of these substances, which have always prevented any unpleasant symptoms from following their administration. Where idiosyncrasy, also, has stood in the way of their exhibition, I found these medicines prevent any sinking and distress, and to remove these effects when they have appeared. There can be no doubt, therefore, that these remedies are most appropriate in cases of poisoning by colchicum. They may be aided by sinapisms, or terebinthinate embrocations, or epithems over the abdomen, and by mucilaginous or oleaginous draughts and injections, which may be made the vehicles of the remedies just advised.

423. iv. HELLEBORE.—*Black Hellebore*, *Helleborus Niger*—*White Hellebore*, *Veratrum Album*—*Veratrum Sabadilla*—*Veratrine*—*Veratria*.—The operation of black hellebore and of veratrum is nearly similar; and the alkaloid of the latter—*veratria*—produces the same action as either of these, a much smaller quantity being required to produce the same amount of effect.—A. *Black hellebore*, in poisonous doses, causes a burning pain in the stomach and intestines, vomitings, purging, cramps in the lower extremities, cold sweats, faintness, paralysis, sometimes insensibility from exhaustion or vital depression, and extreme weakness of the

pulse. Death appears to result from the excessive vomitings and purging, and impaired irritability and action of the heart.

424. *B. White hellebore*—*Veratrum album*—acts as a local irritant, exciting at the same time the nerves of the part. In excessive doses, it irritates the digestive mucous surface, and depresses nervous and vital power. The symptoms are violent vomiting and purging, sometimes of blood; tenesmus, and griping pains in the bowels. These are preceded or attended by a burning sensation in the mouth, throat, and œsophagus; constriction of the throat, with a sense of strangulation; and are soon followed by a small or almost imperceptible pulse; by faintness, cold sweats, tremblings, giddiness, loss of voice, blindness, and dilated pupils, insensibility, syncope or convulsions terminating life. In some cases, noticed by Dr. PEREIRA as having occurred to Dr. RAYNER, these symptoms were present, with the exception of purging.

425. *C. Veratria* is poisonous in very small doses. Mr. TAYLOR states that a physician prescribed for a lady one grain of veratria divided into fifty pills, and three were directed to be taken for a dose. Not long after the first dose had been swallowed she was found insensible, the surface cold, the pulse failing, and with other symptoms of approaching dissolution. She remained some hours in a doubtful state, but ultimately recovered. If the veratria was well mixed in the pills, the dose was here not large; but this admits of doubt.

426. *D. The treatment* of poisoning by these substances is similar to that recommended for other poisons belonging to this class. After the evacuation of the poison, the effects should be attempted to be removed by means of stimulants conjoined with opium. In a case treated by Dr. PEREIRA, the infusion of nutgalls seemed to give relief. Coffee has been recommended both as a drink and as a clyster. The external applications already advised in similar circumstances should not be withheld. Demulcents should be made the vehicles for stimulants, astringents, and opiates.

427. *v. Food Poisons*—*Poisonous Food*—*Poisonous Fish*—*Poisonous Meats*—*Poisonous Cheese*.—Various articles of food not infrequently occasion injurious effects, and even death in a few hours. The slighter effects have sometimes arisen from idiosyncrasy; but not so frequently as supposed by some writers. This cause may be admitted in respect of those instances which have sometimes occurred of a single person only having been affected, of several who have partaken of the same article or dish. Poisonous articles of food—fish, meats, &c.—have hitherto been classed as *acro-narcotics*. As they are more or less irritant, and as acrid and irritant convey ideas nearly related, the first part of the appellation somewhat approaches the truth; but that they produce narcotic or stupefying effects cannot be so readily conceded, inasmuch as this particular effect no farther appears than as it results in some instances from the sinking of vital and cerebral power, and the diminution of sensibility owing to this state. These poisons, in truth, act as irritants of the alimentary canal, and as sedatives or depressants, or paralyzers of organic nervous or vital energy. While they irritate the mu-

cous surfaces, and glandular apparatus of that surface, they rapidly depress vital power; and the irritation they occasion passes not into inflammatory action, but into excessive secretion and exhalation; or, if inflammatory action be developed, it is of an asthenic and spreading form. That these poisons do not act locally only, may be inferred from the ultimate effects being much more serious in most instances than the amount of local lesion can explain; from their contaminating nature, from the ready imbibition of them by mucous surfaces, and from their speedy absorption from these surfaces. The various articles which are sometimes productive of poisonous effects occasion modified or even different symptoms; but they are remedied by very nearly the same means.

428. *A. Poisonous Fish*.—Several species of fish, both in this climate and between the tropics, are always poisonous; and others are injurious only occasionally or rarely. Some accounts of the poisonous fishes of the tropics have been given by Drs. THOMAS, CHISHOLM, and FERGUSON; and various memoirs and notices of the poisonous fish found in Europe have been published by Dr. BURROWS, Dr. COMBE, Dr. EDWARDS, Professor ORFILA, and Professor CHRISTISON. I had occasion many years ago, within the tropics, to treat a case of poisoning by fish, which nearly proved fatal; and I have seen two or three instances of poisoning by mussels in this country; but there was no danger in these cases, although the symptoms were severe. The fish which are the most frequently injurious in this country are all the kinds of edible shell-fish, especially mussels, cockles, periwinkles, lobsters, crabs, and craw-fish. And either of these, when kept too long after having been boiled, or when only parboiled and reboiled after various intervals, as sometimes practiced by the lower dealers, will produce more or less disorder. Salmon and eels are also sometimes poisonous, but the former is injurious chiefly when out of season, or when insufficiently preserved.

429. *a. The symptoms* produced by poisonous fish differ much in different persons; and certain of the effects observed are more or less owing to idiosyncrasy; but the most violent and fatal operation is not so frequently, if at all, owing to this cause.—(a) Thirty persons were poisoned by mussels in Leith in 1827, and of these two died. The symptoms were carefully observed and described by Dr. COMBE. No one complained of anything peculiar in the smell or taste of the mussels, and none suffered immediately after eating them. An hour or two or more elapsed, and then the bad effects consisted rather in uneasy feelings and debility, than in distress referable to the stomach. After eating two or three, and various numbers above this, the lowest number, slight tension at the stomach, with heat and constriction of the mouth and throat, was complained of. These were succeeded by a difficulty of swallowing and speaking freely, by prickly feelings in the hands; by numbness about the mouth, gradually extending to the arms, with great debility of the limbs. Two or three had cardialgia, nausea, and vomiting; but these were not general or lasting symptoms. The muscular debility was present in all the cases. An unpleasant taste was felt in the mouth. There was slight

pain in the abdomen, on pressure, especially in the region of the bladder. The secretion of urine was suspended in some cases, in others it was free, but passed with pain or effort. The action of the heart was feeble, and the breathing unaffected. The face was pale, and expressive of anxiety; the surface somewhat cold, the mental faculties unimpaired. One of the two fatal cases died in three hours, the other in six or seven hours. In one case only did the symptoms of irritation pass into those of inflammation of the digestive canal. The instance which was treated by me within the tropics was characterized by constant vomiting, by remarkable loss of muscular power, by rapid failure of the heart's action, coldness and clamminess of the surface, and sinking, with intermissions of the pulse. This form of fish poisoning may be called the *paralytic*, or vitally depressing, this condition predominating over the irritant.

[We have known vomiting, and all the symptoms of acrid, irritant poisons, produced by eating of halibut, crabs, lobsters, oysters (out of season), mussels, &c. In one instance, a family of six were poisoned by eating mussels, of which one died, with all the symptoms of aggravated cholera morbus. Dr. A. C. Post has reported a case of poisoning, from eating a portion of the liver of the halibut, in the *New York Journal of Med.*, vol. i., p. 101. The patient was attacked soon after eating with pains, nausea, vomiting, and headache; and soon after the skin began to exfoliate from his face, and successively from every part of the body. The disease went off in a few days under the use of diaphoretics and the warm bath.]

430. (b) In the other form of poisoning by fish, cutaneous eruptions, with or without asthma, or asthmatic symptoms without external eruption, are generally present, and signs of local or general irritation predominate. From one to two or three hours after eating the fish, especially mussels, uneasiness, or sense of weight at the epigastrium; heat, and constriction of the mouth and throat, with thirst; numbness, prickings, and itchings of the surface, particularly of the extremities; difficulty of breathing, lachrymation and swelling of the eyelids, and an eruption resembling urticaria are complained of; but sometimes the eruption is papular, sometimes vesicular, and it is always attended by heat and itching. These symptoms are sometimes attended by vomitings, by colicky pains and diarrhœa; but these are often absent, or of short continuance. In the cases related by MOHRING, the eruption was preceded by dyspnœa, lividity of the face, insensibility, and convulsions. In Dr. BURROWS's cases, the symptoms began with dyspnœa, nettle-rash, and swelling of the face, conjoined with vomiting and colic; delirium and convulsions supervened, and death took place in three days. In MOHRING's cases the symptoms appeared in a few minutes; in those by Dr. BURROWS not until twenty-four hours after eating.

431. (c) Fish kept too long before or after having been cooked, or otherwise spoiled, especially salmon and shell-fish, has, in two or three instances which I have observed, produced symptoms differing more or less from the two forms of fish poisoning now described. The poison causing the above effects exists in the fish when cooked, is present in the fresh or live

state, and is not produced by changes that have taken place, either after death or after cooking. But the injurious effects occasioned by such changes as occur after the death, or the cooking of the fish, are different from the foregoing; and are not attended by either the rapid sinking of vital power on the one hand, or the dyspnœa and eruption on the other. The injurious operation in the circumstances now stated, very much resembles an attack of colic, with vomiting, or an attack of cholera; there being generally severe vomiting with griping pains, occasionally purging with cramps of the extremities, much debility, and sinking of the pulse; but these latter symptoms are not so severe as in the first form, and death has not occurred in any of the cases which I have seen.

432. b. The source of the poison, in these cases and forms of fish poisoning which are produced by fresh fish, has been a matter of speculation. In the numerous cases observed by Dr. COMBE the mussels were fresh, plump, and healthy-looking; and Dr. CHRISTISON analyzed some of those which were taken from the stomach of one of his patients without being able to detect a trace of copper, to which the poisonous operation of fish has been attributed. That idiosyncrasy has, as Dr. EDWARDS contends, something to do with the injurious effects of fish, is true in few or rare instances. Dr. CHRISTISON remarks, that a relation of his could not partake of salmon, trout, herring, turbot, or lobster, without being attacked with violent vomiting; and several instances of the kind have been mentioned to me by persons who have possessed this peculiarity; to which, however, fish poisoning cannot be imputed in the great majority of cases. In the nearly fatal case seen and treated by me in a most intimate friend now living, who was never disordered by any kind of fish on any other occasion, and has always been in the habit of partaking freely of every kind of fish, no such idiosyncrasy existed. The mussels, which proved to be poisonous to thirty persons in Leith, were minutely examined by Drs. CHRISTISON, COMBE, and COLDSTREAM; and it would appear that nothing particular was detected in their appearance; excepting that the liver appeared much larger, darker, and more brittle than in the wholesome fish. The poisonous mussels were all taken from one spot, and every person who partook of them was more or less severely affected, according to the number who ate of them. Animals suffered as severely as man, a cat and dog having been killed by them. It is very probable that, as respects these mussels, and perhaps also as regards some other shell-fish, the poisonous principle exists in the liver, as suggested by the statement of Dr. CHRISTISON, but what that principle is has not been ascertained. In the cases of poisoning of two women by mussels, M. BOUCHARDAT states, that he detected sufficient copper to account for the effects; but it is not detected in most cases, and even when present, the quantity found is too small to account for the poisonous effects on the human subject. There can be no doubt, as I have suggested above, that much of the injurious effects of various kinds of shell-fish, eels, &c., arise from a sickly state, produced by the means used to bring them alive to market, and that the choleric and colicky symptoms described (§ 431) as

being often produced by salmon and other kinds of fish, arising chiefly from changes subsequent to the death and cooking or preserving of the fish.

433. *c. The treatment of fish poisoning* should depend much upon the time that has elapsed from the eating of the fish until the commencement of the symptoms; and this may vary from a few minutes to twenty-four hours, or even more. If the period has been short, and the fish still remains in the stomach, an active emetic, as mustard, or the sulphate of zinc, should be given with a large dose of capsicum, and the vomiting encouraged by means of diluents, conjoined with stimulants, aromatics, spices, &c. The elapse even of a long period between the ingestion of the fish and the appearance of disorder, should not prevent a recourse to emetics, for the fish may, in its poisonous state, remain long unchanged in the stomach. If vomiting has taken place without the aid of an emetic, it should not be considered sufficient unless there has been an abundant discharge of undigested or other matters, the treatment now advised being required nevertheless. If the irritability of the stomach become excessive, it will be of no avail to attempt to remove it by means of opium and effervescing draughts, unless they be conjoined with powerful stimuli and warm spices; for this state of the stomach is always in fish poisoning attended by sinking of the vital powers, especially of the heart's action, and by colicky pains and flatulent distention of the bowels. Powerful stimulants, aided by warm embrocations, rubefacient epithems, or sinapisms, over the epigastrium and extremities, are then required. I believe that capsicum—the true cayenne—or small bird-pepper—is an antidote to fish poison, when taken freely. In the nearly fatal case, which I treated within the tropics (§ 429), after other means had failed to allay the vomitings and rally the powers of life, and after brandy and water had been thrown off the stomach, a teaspoonful of powdered cayenne was mixed in a tumblerful of brandy and water (equal parts of each), and taken at a draught. All the symptoms were instantly mitigated, and the next day nothing more than debility was complained of. That the constant vomitings attending this and some other states of poisoning is owing to more than irritation—is owing in some degree to exhaustion of vital power, is shown by the instant arrest of both the nausea and the vomitings by so powerful an excitant as that now mentioned, and which I have prescribed in somewhat similar conditions with equal advantage. I have employed this spice, especially in an early part of my practice, and in malignant diseases, in very large doses, believing that it is not so irritating to the stomach as its impression on the nerves of the mouth and palate would indicate, but that, on the contrary, it imparts a salutary stimulus to the digestive canal, and counteracts the influence of many depressing agents. If the poisonous fish have passed into the bowels, causing colicky pains, flatulent distention of the abdomen, and sinking of the vital powers, enemata, containing spirits of turpentine, with castor oil; and, in extreme cases, asafoetida or capsicum, or both, should be administered and repeated, according to circumstances, and the warm turpentine embrocation or epithem ought to be applied over the abdomen.

434. *B. POISONOUS MEATS.*—Certain kinds of meat are sometimes poisonous even in a fresh state, independently of any disease. Others are poisonous owing to some disease of the animal at the time of death. Others, again, are injurious in consequence of changes which have occurred after the animal has been killed—these changes arising either from the deposit of the ova; or exuviae of insects—from fly-blowing, or from decomposition, or the more slowly developed combinations of the elementary particles which take place in imperfectly preserved or salted provisions, especially in sausages, dried meats, bacon, &c. The secretions of certain animals are poisonous during their lives, especially those possessed by them for the purposes of self-preservation; and the fluids and secretions of others are sometimes poisonous, both during life and after death, owing to the nature of the disease of which these animals are the subject. These latter infect the healthy, contaminating the fluids and soft solids. They are fully considered in the articles BLOOD, DISEASE, and INFECTIO, and in those devoted to the specific forms of disease to which they give rise. Some notice is also taken of certain of them when treating of *Septic Poisons*.

435. *a. Fresh pork* is often injurious, and gives rise to various symptoms, according to the idiosyncrasy of the individual and to the manner in which the animal had been fed. In the East, especially in warm climates, pork is often injurious, and productive of diarrhoea and dysentery; effects which I have seen caused by it in several instances in this country. The Mosaic law forbade the use of it; and there can be no doubt of the wisdom of this law as respects warm countries, and I believe as regards all countries. The *poisonous effects* of fresh pork vary. In the most severe cases it has produced a dry and burning sensation in the throat, with heat and pain in the stomach, retchings and vomiting; a sense of sinking at the epigastrium; a weak, small, and irregular pulse; coldness of the extremities, a cold and clammy perspiration, and colicky pains in the abdomen and around the umbilicus. In other cases the pain has been confined to the stomach alone, or it has been situated in some other part of the abdomen. In addition to these symptoms, there have sometimes been remarkable swelling of the face extending over the scalp without any vesication or redness, swelling and tenderness of the abdomen, an eruption resembling urticaria over the breast, legs, and arms, and a quick, sharp pulse. In rarer instances, there have been neither retchings nor vomitings, but severe colicky pains, and sinking of the pulse and vital powers. Such were the more acute cases of poisoning with pork, and of which Dr. McDEVITT has detailed six cases, all of which were produced by fresh or recently salted pork, and especially by roasted pork. He believes that the injurious effects are produced chiefly by the fatty parts; but I have reason to believe that the viscera are still oftener injurious. [In this country, a preparation of pork called *head-cheese* is more frequently injurious than any other variety of this food, and this is probably owing to incipient decomposition in the centre, as in the case of the German sausages.]

436. The symptoms may appear any time from three or four to thirty hours after the in

gestion of the meat. When the symptoms are delayed until seven or eight hours after the pork has been eaten, they much resemble those of either violent colic or enteritis, and are attended by a sense of sinking or of impending dissolution, and a weak, intermitting pulse, &c. In other cases, especially when a longer period than this has elapsed from the ingestion of the poisonous food—from twelve to twenty-four hours—diarrhœa, or an attack resembling cholera, or dysenteric symptoms of a severe character, have taken place. In many instances the symptoms are slight, especially when the offending article has been evacuated speedily by vomiting or by copious evacuations from the bowels; and even when the symptoms assume an alarming character, the discharge of it, when fully accomplished, is followed by immediate relief of all the symptoms. When only one, of several of those who have partaken of this food, has been thus affected, then we may infer either that the affection is owing to idiosyncrasy, or that the part eaten by the individual has been tainted or otherwise changed; but I am acquainted with occasions on which great numbers of persons, as a large portion of a regiment of troops, have been affected after eating fresh pork, some very severely, with the symptoms above described, or with diarrhœa, or colic, or dysentery.

437. *b. Bacon* seldom produces symptoms of *acro-sedative* poisoning unless those parts of it generally on or near to the surface, which have undergone change during the process of preserving, or near the large vessels. Mr. TAYLOR states, that one fatal case from poisoning by bacon occurred in the metropolis in 1836; and I have seen very severe effects produced by a minute portion of a spoiled or rusty part of ham or bacon having been swallowed. But equally severe and nearly similar symptoms have followed the ingestion of a very small piece of either *mutton* or *veal*, when fly-blown or otherwise changed. Mr. TAYLOR states, that meat of any kind, when too recently killed or decayed, may produce severe effects, and even death. I believe, however, that decay, unless far advanced or connected with the deposition of the ova or exuviae of insects, or the generation of mouldiness, or the lowest forms of animal life in the preserved articles, will not produce of itself the severe symptoms constituting acute or fatal poisoning.

438. *c. Animal substances of various kinds* have become poisonous, owing to changes during their preservation, which Dr. CHRISTISON has called a "*modified putrefaction*." In Germany and other countries, where animal substances are preserved by drying and smoking chiefly, and without much salt, some unknown injurious principle appears to be developed in these substances from the combinations of their elementary particles during the process of preservation. The articles in which these injurious changes have been observed are sausages, bacon, and hams, dried mutton and beef, cheese, smoked salmon, and various other dried or preserved animal substances.

439. *(a) Sausages* have proved most frequently poisonous; but it is possible that they may, at least in some instances, have possessed this property independently of any changes during their preservation, and that it may have existed

in the flesh or viscera of the animal, especially the pork, when quite fresh, of which the sausages were made. This circumstance is rendered the more probable by the accounts of three cases which terminated fatally from the effects of sausages made with the liver of an apparently healthy pig slaughtered only a week before. The inspection of the bodies threw no light on the more immediate cause of death in these cases. (*Lond. Med. Gaz.*, November, 1842.) But the poisonous effects so frequently observed in Germany to be produced by sausages more evidently are developed by a modified putrefaction or by a combination of the elementary particles, taking place during the process of preservation, and different from the usual states of putrefaction. The sausage poison has been described by Dr. CHRISTISON from the materials furnished by KERNER, DANN, and HORN. In a period of little more than thirty years, 234 cases of sausage poisoning occurred in the state of Würtemberg, and of that number 110 proved fatal. Those sausages which have been found poisonous have usually been of large size, and cured by drying and smoking with wood. They become deleterious in the spring after they have been long kept, and been alternately frozen and thawed; and are poisonous only at a particular stage of decay, and cease to be so when putrefaction has fully advanced. Those that are poisonous possess an acid reaction, are soft, have a nauseous putrid taste, and an unpleasant sweetish-sour smell. The central parts are chiefly deleterious, these parts being poisonous even when the surface is wholesome.

440. *(b) The poison of cheese*, as observed in several Continental countries, and rarely in this, appears to be developed by analogous changes in the curd to those observed in sausages; and is more properly developed by a partial decomposition having taken place in the curd before it was subjected to pressure, than by any change subsequently to this process. Dr. CHRISTISON thinks that the cheese poison is occasionally met with in Cheshire, where among the small hill-farms the limited extent of the dairies obliges much of the curd to be kept for several days before the quantity required for large cheeses is accumulated.

441. *d. The symptoms* produced by spoiled *sausages, cheese, bacon, hams, and salmon*, which has become partially decomposed before, or after being cured, are probably very nearly the same in respect of each of these articles; but they have been more frequently and precisely observed and described as regards the ingestion of spoiled sausages. Generally, the effects of these are not manifested until twenty-four hours, or two, three, or even four days after they have been eaten. This tardiness of operation is probably owing to the difficulty of digesting them, and the slowness of their absorption. The first symptoms are pain in the stomach, vomiting, purging, dryness of the mouth and nose, and hoarseness or loss of voice. Deglutition becomes difficult and painful; the pulse fails, swoonings ensue, and the skin is cold and ultimately insensible. The eyes, eyelids, and pupils are almost motionless. The secretions and excretions are at last suspended, but often profuse diarrhœa continues throughout. Fever is rarely present, and the mind continues unaffected. Fatal cases end with convulsions and

oppressed breathing between the third and eighth day. In cases of recovery, convalescence is very long protracted.

442. *c. The appearances on dissection* have been described as observed in cases of sausage poisoning. There are usually signs of inflammatory irritation in the internal surface of the digestive canal. The throat is white and dry; the œsophagus thickened; the stomach and intestines reddened, and croupy exudations are formed on the surface of the trachea. The heart is flaccid, and the body is said to resist putrefaction. But it is evident, from this account, that the structural changes consequent upon poisoning by these articles of food have not been observed with due care and precision.

443. *f. The treatment of poisoning by pork, or by sausages, preserved meats, and other articles too long kept or imperfectly preserved*, should not differ materially from that recommended for fish poison. The chief indication is to procure the discharge of the offending substance as speedily as possible, by means of the emetics conjoined with the warm spices already mentioned (§ 433). If it be inferred that it has passed the pylorus, the enemata advised for fish poison, and the external applications also recommended, should be resorted to. In cases of poisoning by these substances, *creasote*, conjoined with warm spices, with small doses of opium, and with ipecacuanha if diarrhœa or dysenteric symptoms appear, will be found of great service, especially when the stomach becomes irritable. In most cases, also, mustard poultices, or turpentine epithems, over the epigastrium or abdomen, will be of service; and they ought never to be omitted in the more acute and dangerous cases.

444. *C. DISEASED ANIMAL SUBSTANCES, FLUIDS, SECRETIONS, &c.*—*a. The flesh of over-driven animals*, especially if these animals have been deprived of drink for some time before they were killed, and probably also their viscera, produce injurious effects, especially in cachectic constitutions. But, according to the experiments of M. MORAND, the flesh of such animals is perfectly wholesome when cooked and eaten, although the application of the blood, or raw flesh, to a scratch or wound, or even to the sound skin, is often followed by dangerous or fatal effects: sometimes consisting of an eruption of gangrenous boils, the *pustule malignes* of the French, at other times appearing as diffuse inflammation of the skin, or of the cellular membrane, or of both.

445. *b. The viscera and offal of animals* occasionally produce analogous effects to these just mentioned, even on the unabraded surface. Sir B. BRODIE has shown that the contact of these with abraded or wounded parts may cause chronic states of erysipelas, &c. I have seen several instances of the scratches or pricks of the fingers of cooks by the bones of hares or of other animals, and even abrasions of the skin, having been followed by inflammation of the absorbents or of the veins, or by diffusive inflammation of the cellular tissue.

446. *c. The flesh or viscera of diseased animals*, and especially of those which have died of epidemic or epidemic distempers, are undoubtedly injurious, and even in some instances rapidly fatal. Mr. TAYLOR states, that four members of a family in Oxfordshire, in the spring of 1841,

dined in good health upon part of a sheep which had died of a disease then prevalent among cattle. The symptoms which followed this meal resembled those of irritant poisoning, accompanied by others indicating an affection of the nervous system. One of the patients, a child, died in less than three hours; the others recovered. There was no poison discovered in the food, nor in the body, nor was any poisonous vegetable used at the meal. (*Op. cit.*, p. 214.)

447. *d. There are certain districts in North America*, in which the *milk and flesh of animals*, especially cattle, acquire poisonous properties from the grass [or some vegetable] on which they feed. The disease thus produced in persons who partake of this poisonous food has been named in America the “milk-sickness,” or “trembles.” These districts lie to the west of the Alleghanies, and those who venture within them are obliged to abstain from the flesh of the cattle within the same limits, as well as from the milk and its preparations. It appears from the report of Drs. HOSACK, POST, and CHILTON, that the inhabitants of some of these districts, with a reckless disregard of human life, carry the butter and cheese, which they dare not themselves eat, to markets at a distance; and that thus symptoms of poisoning, and even death, for which the medical attendant cannot account, are frequently produced. According to the same report, the cattle from these districts are sent in great droves over the mountains, hut, in order to deceive the purchasers, they are sent to New York by a southern route. The flesh of these animals occasions aggravated symptoms of cholera. “The viscera of these cattle are often found diseased; the livers most generally so.” Owing to the symptoms of poisoning which have followed the use of beef, butter, and cheese from these districts, the American government caused a medical inquiry to be instituted into the matter, and the reporters recommended the sale of these articles to be prohibited. In the event of this recommendation being adopted, it is not improbable that the poisonous food may be exported to England. (*See Edin. Med. & Surg. Journ. for July, 1844.*)

[Cases of poisoning by eating smoked beef, cheese, head-cheese, and ham, are not of unfrequent occurrence in this city. In December, 1841, about forty cases of poisoning from eating smoked beef occurred in a particular neighbourhood, all of which could be traced to the same source. About nine hours after partaking of the food, pain and uneasiness were experienced at the præcordial region, which, extending to the back and loins, were only temporarily relieved by the dejections which followed: vomiting now supervened, attended with great thirst and a burning sensation at the pit of the stomach; indeed, the irritability of this organ soon became so great, that no substance, either as food or medicine, could be retained by it for an instant. These symptoms soon assumed the most aggravated form; extreme prostration followed; the functions of the nervous, muscular, and digestive systems were much impaired, and the period of convalescence was very protracted and tedious. In one case only did the attack prove fatal. There can be no doubt, I think, that the poison was generated by partial decomposition after the death of the

animal; or it is possible that the animal which furnished the beef was diseased. Analysis proved that the beef contained no mineral or vegetable poison. A decoction made from it, when thrown into the circulation, caused death in about three hours and a half; while a similar preparation, made from sound beef, produced no morbid signs in the animal experimented on.

A peculiar endemic prevails in certain portions of the Western States, called the *milk-sickness*, or *trembles*. The former name has its origin in the circumstance that the disease is frequently communicated to man by the use of the milk or butter of an infected animal, though it will be as readily produced by eating the flesh; and the latter name arose from the symptoms of a *trembling motion* of the voluntary muscles manifested in cattle. Horses as well as cattle die by the poison, and dogs, cats, buzzards, turkeys, chickens, and crows die by eating the flesh of animals that have perished by this disease. Sometimes the animals are affected to that degree that their flesh and milk will produce the disease in man, and yet they themselves manifest no unhealthy symptoms whatever. (*American Med. Recorder*, vol. vi., p. 257). Dr. GRAFF, of Edgar county, Illinois, says, "Hundreds of persons throughout the West and Southwest are annually perishing from its attacks. Butter and cheese manufactured from the milk drawn from the infected cows are supposed to be the most concentrated forms of this poison. They possess no distinguishing appearance, colour, or taste from the healthy article. A very minute quantity of either will suffice to develop the disease in man. The cream ordinarily be added to the coffee drank at a single meal is said to have induced an attack. The butter or cheese eaten at one repast has frequently been known to prove effective. The property is not contained in any of the elements of the milk exclusively, but distributed throughout the whole of them, being possessed by the buttermilk as well as the whey." The same writer remarks (*Am. Jour. Med. Sciences*, 1841), "That a murderous practice is now carried on in certain districts, in which the inhabitants will not themselves consume the butter and cheese manufactured, but, with little solicitude for the lives or the health of others, they send it in large quantities to be sold in the cities of the West, particularly Louisville, Kentucky, and St. Louis, Missouri." The committee who reported upon the subject of poisoned beef, already referred to, Dr. FRANCIS, chairman, observe, "From the inquiries which we have made, we have ascertained that immense droves come from the West to supply our markets; they are driven across the mountains and reach New York from the south; hence they are called by the dealers 'Southern cattle.' Many of these cattle become diseased on the route, and are then exchanged for the pasturage of the herd. In this condition they are frequently slaughtered by the farmers, the flesh sent to the city and exposed for sale, producing in persons who make use of it symptoms of aggravated cholera morbus. Physicians attest that they have frequently met with such cases, which it was impossible to account for in any other way." It is a well-known fact that the liver, in southern and western cattle, is very liable to

be diseased; so much so that it is always cast away, it being actually unknown as an article of diet. The late Dr. FERRY observes (*N. Y. Journ. of Med.*, Nov., 1843), "Among the cattle of our western country, and especially of Ohio, there are frequently found in the liver the most extraordinary heterologous formations. This viscus is often discovered completely studded with osseous sacs, containing a dark grumous fluid, in which lives a species of entozoa, having physical characters almost identical with the native leech. Of these leeches, as many as fifty or sixty may be found in a single liver, so that not a cubic inch of normal liver remains." The cause of the milk-sickness is as yet unknown, though it is generally attributed to some poisonous vegetable.]

448. The above interesting and important fact is an ample illustration of what has been stated by some physiologists, namely, that certain secretions may acquire poisonous properties from the nature of the ingesta, without the individual appearing to be materially disordered. I have repeatedly had occasion to observe, that the *milk of a nurse* has produced all the symptoms of slow poisoning, occasioning vomiting, diarrhoea, and sinking of vital power, with or without convulsions in the child which she suckled; and that this state of the milk has not been occasioned alone by the nature of the ingesta, but also by the more violent mental emotions. That the nature of the food may thus affect the secretions without materially disordering the animal, is farther shown by the poisonous nature of the *honey* in some districts, as that of Trebizond, which is said to be collected from poisonous plants. I believe that the deleterious effects of pork are chiefly owing to the unwholesome nature of the food upon which the animals had lived for some time before they were slaughtered.

449. *e. Poisonous honey*, especially as met with in Trebizond, causes, according to Mr. ABBOT, violent headache, vomiting, and a condition resembling intoxication. A large dose produces deprivation of all sense and power for some hours afterward. These effects agree with those mentioned by XENOPHON, in his account of the "Retreat of the Ten Thousand." PLINY also takes notice of this poisonous honey. TOURNEFORT ascribes this property to the bees feeding on the *Azalea pontica*. (*Lond. & Edin. Philos. Mag.*, vol. v., p. 314.) The poisonous effects of honey have also been observed in North America, by Drs. BARTON and HOSACK, who consider that the injurious property is owing to the various species of *kalmia*, the *Andromeda mariana*, the *rhododendron*, the *Azalea undiflora*, and the *datura* on which the bees have fed. The symptoms mentioned by Dr. BARTON are dimness of sight, or vertigo, succeeded by a delirium, which is sometimes mild and pleasant, and sometimes ferocious; ebriety, convulsions, with foaming at the mouth; pain in the stomach and intestines, vomiting, purging, and, in a few instances, death. Sometimes vomiting is among the earliest symptoms, and in that case the patient is readily relieved, although a temporary weakness of the limbs remains. (*American Philosoph. Trans.*, vol. v., p. 65.) In the cases recorded by Dr. HOSACK, the chief symptoms were violent vomiting, cold extremities, a livid appearance of the counte-

nance; the pulse having been remarkably reduced. In these instances the honey was of a dark-reddish colour, and of thicker consistence than usual. (*Edin. Philosoph. Journ.*, vol. xiv., p. 91.)

450. *f.* The treatment of poisoning by the *flesh of diseased animals* (§ 444–448), judging from the effects or symptoms as far as they have been described, should not materially differ from that which I have recommended for poisonous fish (§ 433). Having expelled the injurious substance by emetics, and by purgatives and enemata, if it have passed the pylorus, the powers of life should be developed by means of the tonics, stimulants, aromatics, spices, external applications, &c., there prescribed; and especially quinine, camphor, capsicum, and opium. In the cases of *poisoning by honey*, just noticed, the efforts of nature suggested the best remedy, namely, the early discharge of the injurious substance from the stomach and bowels by emetics and purgatives. I believe that, in all cases of poisoning by injurious articles of food, the best purgative that can be employed is, a combination of spirits of turpentine, castor oil, and capsicum, taken on the surface of coffee, or some aromatic water; enemata, containing the same medicines, being also administered according to the circumstances of the case.

451. VI. MINERAL AND SALINE ACRO-SEDATIVES.—A. THE ANTIMONIAL COMPOUNDS act as irritants of the surface or part to which they are applied, and, owing to their absorption chiefly, and probably also to their more immediate influence upon the nervous systems, they depress vital power and vascular action. The *chloride of antimony*, the preparation which is the most corrosive and irritant, has been noticed above (§ 175, *et seq.*), and shown to be injurious principally in consequence of its local effects. But the other official preparations of antimony exert a much more remote and extensive influence, more especially the *potassio-tartrate*, the *sesquioxide*, the *oxysulphuret*, or kermes mineral, and the *compound antimonial powder*, which was intended to represent the empirical powder of Dr. JAMES. The medicinal properties of these preparations differ more or less; but, when given in excessive doses, the first, or the *potassio-tartrate of antimony*, may be considered as representing their injurious effects, both local and constitutional. When treating of it, therefore, my observations will apply also to the other compounds of this metal.

452. *a.* The *antimony-tartrate of potash*, or *potassio-tartrate of antimony*, or *emetic tartar*, is a powerful irritant when applied to any part, or even to the cutaneous surface, in a state of minute division or strong solution; and generally causes an eruption of painful pustules resembling those of ecthyma or small-pox, and various constitutional changes, according to the dose and the mode of employing it. As this preparation is the most prescribed, it is of importance that its *local and remote effects* should be well understood. (*a*) When applied to the *cutaneous surface*, *emetic tartar* gives rise to somewhat different results, according to the mode of its application. In a state of strong solution it occasions an eruption of small semiglobular painful pustules; in that of powder sprinkled over a plaster, or mixed in an oint-

ment, the pustules are larger, and, when fully developed, are flattened, with a central dark point, contain a puriform serum and an albuminous deposit, and are surrounded by an inflammatory border. The central dark point soon extends, and forms a dark crust as desiccation of the pustules advances, that is afterward thrown off. The internal use of this substance in large or poisonous doses sometimes gives rise to a similar pustular eruption, or to aphthous spots, in the mouth, fauces, pharynx, œsophagus, and intestines, but more frequently to redness, and other inflammatory changes in the gastro-intestinal villous surface; attended by pain in the region of the stomach extending over the abdomen, and by vomiting, followed by purging.

453. (*b*) The *constitutional or remote effects* of tartar emetic and other antimonial preparations vary with the dose. In *small doses* emetic tartar increases the secretions of the liver and pancreas, and the secretions and exhalations of the gastro-intestinal villous surface; and as it passes into the circulation, it increases subsequently the perspiration and the mucous and urinary excretions. In *larger doses* it excites nausea and vomiting, relaxes the skin, and augments the mucous secretions and exhalations. In still larger quantities it depresses the organic nervous energy, relaxes the muscular structures and all the tissues, and gives rise to general exhaustion. With its emetic operation it occasions distressing nausea and sinking, and is sometimes uncertain in the amount of its effects, the emetic action being slight, while the depression and diarrhœa produced by it are extreme. *Excessive doses* of this substance have acted as a violent irritating and depressing poison, and produced death, especially in children, and infants when it has been given frequently, and in too large quantities for this class of patients; the sinking of vital power and death, which have in no rare instances ensued, having been mistaken for the progress and result of disease. ORFILA states that in one case a scruple, in another, twenty-seven grains nearly proved fatal, and that forty grains caused death. The symptoms in these were vomitings, pain and tumefaction of the epigastrium extending over the abdomen, hypercatharsis, delirium, convulsions, and, in the fatal case, death on the fourth day.

454. The above should be viewed as the effects of this substance on the healthy body only, for it has been found that, in states of inflammatory excitement, in local inflammations, and fevers attended by high vascular action, the system will tolerate quantities of tartar emetic, which have been productive of the most dangerous effects in other conditions of the œconomy. This salt has been given in enormous doses by RASORI in these states of disease, and the statements of this physician have been partially confirmed by LAENNEC and others. I have attempted, however, to give very large doses of it in pneumonia; but, if I advanced above five or six grains in the twenty-four hours, distressing diarrhœa and depression followed the emetic action of it, and I have been obliged to desist. Some source of fallacy must exist, as regards either the purity of the medicine, or the retention of it in the stomach and bowels, from either of which it may have been more or less

completely rejected; or then we must infer that an excessive quantity of it acts less energetically than a very small dose: an inference which receives no support from the external application of it, or when it is administered or applied so that its operation, especially as an irritant, may be subjected to the senses of the observer. It should, however, be noticed, that in cases of oppression of the brain, and of coma, large doses of this salt may be given without producing vomiting, and, if fever be also present, without occasioning any very remarkable effect, until dangerous sinking of the powers of life, or diarrhoea, or both appear. This is the more apt to occur in children and young subjects, and requires more attention than it has received.

455. The symptoms produced by antimonial taken in poisonous doses are, in the majority of instances, such as have been just described; but when taken in states which may affect the mouth or palate, a strong metallic taste is perceived in the mouth, both at the time of swallowing and afterward; and even during convalescence from large quantities, this taste sometimes continues, with an aphthous eruption in the mouth and fauces. There are generally also syncope, small, weak pulse, great prostration of strength, cold, clammy perspirations, vertigo or tremour; spasms of the extremities, convulsions, in the more dangerous cases; and these symptoms generally precede death in fatal cases. Dr. Beck mentions an instance in which fifteen grains of tartar emetic killed a child. I am confident of having seen fatal effects follow the exhibition of a smaller quantity, given in divided doses, in cases of croup to which I had been called.

456. *L. Tartar emetic*, when injected into the large bowels, or into other mucous canals, produces nearly similar effects to those already described; and is also, in these circumstances, absorbed into the circulation, through the medium of which, as well as when injected into the veins or introduced into wounds, it acts specifically upon the stomach, producing, as M. MAGENDIE has shown, a very decided action on this organ, when thus employed. When applied to the skin, in the form of powder, or of strong solution, to produce an artificial eruption, it rarely occasions any constitutional effects of a severe character, or resembling those occasioned by the ingestion of a poisonous dose. Yet such effects have occurred, and have been attended by nausea and vomitings, and even by diarrhoea.

457. *c. After death*, the villous surface of the stomach and duodenum has been found reddened and covered by a slightly adhering layer of mucus. Mr. TAYLOR states, that in a man who had taken forty grains of tartar emetic within a period of five days, and who then had died apoplectic, the stomach was found much reddened and inflamed in irregular patches, the redness passing into a violet tint; but there was no ulceration of the internal membrane; the duodenum was in a similar state, and the small intestines were but slightly inflamed. In animals poisoned by this substance it is usual to find inflammation of the gastro-intestinal mucous surface.\*

\* [We several years ago reported a case of poisoning by antimony, with the post-mortem appearances, which may be found in Beck's *Med. Jurisprudence*.]

458. *d. Treatment*.—The evacuation of the poison from the stomach by the stomach-pump, or by encouraging vomiting by irritating the fauces, or by the free administration of warm water, milk, or demulcents, should be enforced. Any vegetable infusion containing tannin, or an infusion of green tea, oak bark, or of the yellow cinchona bark, may be given freely; as the tannin combines with oxide of antimony to form an insoluble compound, thereby suspending the operation of the poison. But Dr. PEREIRA states, that although cinchona decomposes emetic tartar, it does not destroy the activity of this salt; for that, in many instances, from one to two grains of the salt were given with the yellow bark, and nevertheless nausea or vomiting occurred. In most instances of poisoning by the preparations of antimony, opium is most beneficial, especially when conjoined with small doses of camphor, and even of capsicum when the depression is urgent. Mustard epithems on the epigastrium, and the warm bath, and several of the other measures advised for the removal of the effects of other substances already considered under this class, will also be found of service.

459. *B. BARYTA AND ITS SALTS* are poisons of which but little is known as to their operation on man. Pure baryta is met with only in the laboratory of the chemist; but it is a caustic poison. The principal salts are the chloride, nitrate, acetate, and carbonate, the last of which is insoluble. The sulphate is said not to be poisonous, as it is insoluble; but, as Mr. TAYLOR remarks, it would be well to establish this by experiment, since insolubility ought not to be received as evidence of the inertness of any substance, although it is erroneously assumed to be so, and is the chief basis of the doctrine of chemical antidotes. Arsenite of copper and calomel are as soluble as the sulphate of baryta, and yet they act powerfully on the body. The instances of poisoning which have occurred from baryta have been caused by the chloride and the carbonate.

460. *a. The symptoms* produced by the chloride of baryta were a combination of irritation of the alimentary canal, and severe affection of the nervous system, especially vertigo, convulsions, and paralysis. In one case half an ounce was fatal in two hours. In another, one ounce destroyed life in an hour. It has been found to affect the system powerfully even in small doses. ORFILA has shown that the chloride of barium is absorbed, especially when given in small or moderate doses. He states that he has found it in the liver, spleen, and kidneys of animals killed by it.

461. The carbonate of baryta is said to have been fatal in two cases, in each of which one drachm only was taken. But, in a case recorded by Dr. WILSON, it appears not to have been nearly so virulent. A young woman swallowed half a tea-cupful of the powdered carbonate mixed with water. She had fasted for twenty-four hours. The powder had no taste. In two hours she had dimness of sight, double vision, ringing in the ears, pain in the head, throbbing in the temples, with a sensation of distention and weight at the epigastrium, and palpitation of the heart. She afterward complained of pain in the legs and knees, and cramps in the calves. She vomited twice a fluid like chalk and water.

The skin was hot and dry, the pulse frequent, full, and hard. These symptoms gradually subsided, and she recovered, although the pain in the head and epigastrium continued long. (*Lond. Med. Gaz.*, xiv., p. 488.)

462. *b.* The morbid appearances produced by the salts of baryta have not been described as they occur in man. In the lower animals the mucous membrane of the stomach is usually found of a deep-red colour, unless death has taken place very rapidly, and in this case the alimentary canal is healthy. In all the animals which in Dr. CAMPBELL's experiments were killed by the chloride applied to wounds, the brain and its membranes were much injected with blood; and in one of them the appearances were those of congestive apoplexy.

463. *c.* The Treatment of poisoning by the salts of baryta consists chiefly in the speedy administration of an alkaline or earthy sulphate, as the sulphate of soda or of magnesia. The poison is thus converted into the insoluble sulphate of baryta, which, if not altogether inert, is nearly so. But the alkaline sulphates are of but little service where the carbonate of baryta has been taken, unless in procuring the more rapid discharge of the poison by the bowels. In Dr. WILSON's case, just mentioned, the copious evacuations from the bowels consequent on the exhibition of the sulphates were evidently beneficial, and tended to the recovery of the patient. Unless the patient be seen early, any treatment will prove inefficacious. Where the carbonate of baryta has been taken, Mr. TAYLOR recommends recourse to emetics and the stomach-pump; or, as chemical antidotes, a mixture of vinegar with an alkaline sulphate.

464. *C. COPPER, THE PREPARATIONS AND COMPOUNDS OF,* have been considered above (§ 205, *et seq.*) with reference to the corrosive and acute action of these substances when administered in large doses or quantities. But in smaller quantities, or in repeated doses, they act locally as irritants of the gastro-intestinal villous surface, and constitutionally as sedatives or paralyzers of nervous and vital power; this latter effect resulting both from the influence primarily produced by them upon the nervous systems, and from their operation, through the medium of the circulation, upon the heart and nervous centres. The cupreous compounds are most likely to act in this way, and in a chronic form, when they contaminate articles of food, as remarked on many occasions. The salts of copper, which are the most frequently administered in large doses for the purposes of suicide and murder, are the *sulphate* and *subacetate*, and these act chiefly as corrosive acute poisons, as stated above (§ 205). But these, as well as the other compounds of this metal, may be so employed or administered as to produce the symptoms most characteristic of *acro-sedative* poisoning.—*a.* In most instances the gastric symptoms are similar to, but not so severe as, those attending the corrosive operation of the poison, while the nervous symptoms are of longer duration. There are generally burning pain in the throat and stomach, anxiety, vomitings, acute pains and great swelling of the abdomen, but no diarrhoea; afterward painful and difficult deglutition, with swelling of the throat and face, oppression of the pulse, salivation and ulceration of the gums, spasms, convulsions, or

paralysis, sometimes jaundice, &c. The irritability of the stomach and cramps, or paralysis, often continue long, and are attended by costiveness and dysuria or suppression of urine.

465. *b.* The *sub-chloride of copper*, oxychloride or Brunswick green, is sometimes formed when common salt has been used in a copper vessel, and in this way, as well as when employed as a pigment, it has given rise to accidental poisoning. A boy of three years swallowed about a scruple of this salt. Vomiting and coldness of the extremities followed, and continued until death. On dissection there was no change indicative of the action of an irritant poison, excepting slight congestion of the vessels of the brain.

466. *c.* Copper vessels are acted upon by articles of food or drink, especially if these articles contain saline substances or acids, or become acid while kept in these vessels. Thus wines which are more or less acid, substances containing vinegar, or any other acid, soups or broths, especially if they contain vegetable matters, and are liable to become acid, and fatty substances, when kept only for a short time in copper utensils, are not infrequently productive of accidental poisoning. FALCONER and others have shown that metallic copper undergoes no change by contact with water unless air be present, when a hydrated carbonate, mixed with oxide, is formed. When an acid, or an oily or fatty matter, is in contact with the metal, then this change more rapidly takes place, and the liquid or fat acquires a green hue. Hence no acid, oily, or saline liquid should be prepared or kept in copper vessels. Nor should fruits, pickles, or preserves be either kept or prepared in them. The quantity of the poison which may be formed in these circumstances may not be sufficient to produce fatal poisoning, but they may be quite enough to cause severe gastro-nervous or acro-sedative effects. GMELIN was consulted respecting a violent disease which prevailed among a whole brotherhood of monks. The symptoms were obstinate and severe colic, retching and bilious vomiting, flatus, costiveness, burning pain in the pit of the stomach, under the sternum, in the region of the kidneys and extremities, with paralytic weakness of the arms. He found, on inquiry, that all the kitchen vessels—the pots, pans, milk pail, and butter dishes—were made of copper. Similar instances of culinary poisoning have been mentioned by CHRISTISON and other writers.

467. *d.* It is stated by Mr. TAYLOR, that the use of the alloy called *German silver*, which is a sort of *white brass*, consisting of copper, zinc, and nickel, and containing about 50 per cent. of copper, may be productive of acro-sedative poisoning where articles, as spoons, made of this alloy, are allowed to remain in contact with acid, oily, fatty, or saline substances. A lady in Paris, in 1838, after having had eels for dinner, was awakened in the night by headache, nausea, followed by vomiting and colic. Her physician ascertained that the eels had been cooked with butter and vinegar in an earthenware vessel; and he found the spoon, which was of German silver, presenting on different parts greenish spots. Chemical analysis showed that a poisonous salt of copper had been thus produced; and the fact was farther proved by

polishing the spoon and placing it in a similar mixture. Half an hour afterward green spots were perceived on the spoon, and in twelve hours it was quite green, as well as the butter in contact with it.

468. *c. Arsenite of copper, or SCHEEL'S Green*, being extensively used as a pigment, both in the arts and in confectionery, has occasioned dangerous effects. Dr. GEOGHAGAN informed Mr. TAYLOR, that fourteen children in Dublin, in 1842, suffered symptoms of poisoning owing to their having eaten confectionery ornaments coloured with this substance; and jaundice followed in two or three of those cases. Three lives were nearly sacrificed at a school near Manchester by the same cause: they suffered from violent vomiting, severe pains in the stomach and bowels, and spasms of the extremities.

469. The green colour of the matters vomited, in cases of poisoning by the cupreous compounds, has been mistaken by some for bilious vomiting. But this colour is generally owing to the poison, and not to the presence of bile in the vomited matters; for the bile is generally obstructed, and the liver and intestines more or less paralyzed by the influence of the poison on the organic nerves, as shown by the jaundice, and by the flatulent and colicky distention of the abdomen in these cases.

470. *f. The modus operandi of the cupreous compounds* appear to vary with the preparation, with the quantity swallowed, and the state of the stomach at the time, as respects especially the quantity and nature of the contents of this viscus. They certainly produce, as shown above (§ 207), a corrosive action on this organ when taken in large quantities, and in other circumstances favourable to that action; while, in other cases, this action is but slight, the fatal issue chiefly resulting from the change produced by them in the nervous system. Their organic action, or the disorganization produced by them locally, is mainly owing to their chemical combination with the albumen, or with one or more of the animal tissues. They evidently, also, affect the nerves of the part with which they come in contact, altering the innervation of the surface or viscus. They are also more or less imbibed by the surfaces and tissues, and carried into the circulation, thereby farther depressing and otherwise changing the irritability and innervation of the structures, the poisonous action of the cupreous salts being produced in this way chiefly, especially when given in repeated doses, or applied to a wound, as shown by the absence of corrosive or other local effects, and by the fact of these salts having been detected in the blood and viscera of animals poisoned by them. Dr. DUNCAN found that the application of the sulphate to a wound produced death in twenty-two hours, and yet the body appeared everywhere in a healthy state; but SMITH and ORFILA state that the acetate applied to wounds caused only local inflammation.

471. *g. The diagnosis of cupreous poisoning* is of some importance, seeing that the symptoms caused by it closely resemble those produced by arsenic and corrosive sublimate. According to ORFILA, the first symptom occasioned by the compounds or salts of copper is violent headache, which is followed by vomiting and cutting pain in the bowels, and by cramps and

pains in the legs and thighs. Generally there is a coppery taste in the mouth and throat, and an aversion from the smell of copper. Jaundice is a common symptom, and is never observed in poisoning by arsenic or sublimate. Fatal cases terminate with palsy, insensibility, and convulsions. This order of the symptoms is, however, by no means generally observed; for the headache often does not appear until after the vomiting; and the paralytic state, either of the sensibility or the power of motion, is often early. The chief diagnostic signs on which any reliance can be placed, are the coppery taste of the mouth, with a peculiar astringency and watering of the throat, with ulceration in the more chronic cases; vomitings and eructations of greenish, or greenish-blue matters, and frequently jaundice, or slight yellowness of the surface, which, however, does not appear in some cases until after death.

472. Cupreous substances, when taken in minute quantities for a long time, or when used by workmen who are inattentive to cleanliness, according to the observations of PATISSIER, MORAT, and others, are productive of a greenish sallow hue of the countenance; of an infirm and decrepit state of the body; and of severe attacks of colic, with partial or slight palsy; the children of persons thus rendered infirm being rickety and puny.

473. *h. The appearances on dissection of fatal cases* are most varied and uncertain. In some, the corrosive action of the poison already described (§ 207) is the most remarkable, especially in the stomach and duodenum. In others, equally or even more rapidly fatal, little or no structural change of these viscera is observed; nor even inflammatory appearances of the stomach and bowels are met with. In the majority of instances, however, the alimentary canal is more or less inflamed; and it very commonly presents a greenish hue, especially the stomach, œsophagus, and duodenum. The external surface is generally jaundiced or slightly yellow. The blood is of a dark hue, and fluid in some cases, and coagulated in others. The lungs and the sinuses of the brain are more or less congested; and the brain is sometimes more vascular than usual.

474. *i. The Treatment of the slow or acro-sedative form of poisoning by cupreous substances* should be based chiefly on the method stated above (§ 208, *et seq.*). After the evacuation of the poisonous substances as there advised, albuminous and saccharine substances should be given, and irritability of the stomach ought to be quieted, as it tends remarkably to lower the depressed vitality of the frame, by opium conjoined with camphor and creasote, and by external derivatives applied over the epigastric region. If inflammatory action be manifested, the usual local and general measures indicated by the state and associations of this condition ought to be prescribed.

475. *D. SALTS OF POTASH.—a. Chromate of Potash.—Chrome—Bi-chromate of Potash.*—This salt is extensively used in dyeing; yet poisoning by it is rare; but instances have been recently recorded. A concentrated solution of it causes all the symptoms and structural changes of corrosive poisons. In small doses it occasions vomiting, diarrhœa, paralysis, and death in the course of some hours. It appears to be

more or less absorbed, and to depress and otherwise affect nervous and vital power. In a case described by Mr. WILSON, of Leeds (*Lond. Med. Gaz.*, vol. xxxiii., p. 734), where a large quantity of this poison had been taken, the poisoned person not having been seen until soon after death, the countenance was pale, placid, and composed; the eyes and mouth closed; the pupils dilated; no marks of vomiting or diarrhoea, nor discharge from any of the outlets of the body, nor any stain upon his hands or person, or upon the bed linen, or furniture, could be detected. On dissection, a pint of turbid, inky fluid was found in the stomach. The mucous membrane of this organ was red and very vascular, particularly about the cardiac orifice. The brain, its membranes, and all the other viscera were quite healthy. The contents of the stomach furnished the chromate on analysis. In this case the chrome produced neither vomiting nor purging, and did not act by any irritating influence; but by its sedative action entirely. Hence it may be viewed as causing, according to the dose, state of the stomach, and other circumstances, either a decided corrosive effect, or an acro-sedative action, or even a purely sedative or fatally depressing operation. The treatment appropriate to poisoning with this salt is recourse to emetics or the stomach-pump, and to the administration of magnesia or chalk, mixed in water.

476. *b. Nitrate of Potass.*—TARTRA denies that this salt possesses any poisonous properties; and it is stated to have been given, for medicinal purposes, in doses varying from six to twelve or even sixteen drachms in the twenty-four hours. (*Med. Chirurg. Rev.*, April, 1844, p. 549.) As it is much employed in the arts, accidents occasionally occur from it; and, in a large dose, as when taken in mistake for some purging salt, serious or even fatal results may be produced by it, although its effects are somewhat uncertain. Two men swallowed each one ounce of nitre by mistake for GLAUBER's salt, and almost instantly experienced a sense of coldness in the course of the spine, trembling in the limbs, with vomiting and purging; the stools were bloody. They recovered in the course of a few days. In another case recorded in the same work, an ounce of nitre was fatal in thirty-six hours. (*CASPER'S Wochenschrift*, b. xviii., 1841.)

477. The symptoms and structural lesions produced by a poisonous dose of this salt will appear from the following details: M. ORFILA states that a lady took an ounce of nitre by mistake, and in a quarter of an hour suffered nausea, vomiting, and purging; and the muscles of the face were convulsed, the pulse weak, respiration laborious, and the extremities cold; but there was a burning pain in the epigastrium. She died three hours after taking the salt. On dissection, the stomach was found inflamed and the villous coat detached in places. Near the pylorus the inflammation approached to gangrene. A large quantity of fluid, coloured with blood, was found in the stomach. Dr. GEOGHEGAN communicated to Mr. TAYLOR the following case: A man took, by mistake for salts, from an ounce to an ounce and a half of nitre. Severe pain in the stomach followed, with violent vomiting, but no purging. He died in about two hours after taking the salt. On examination, a

bloody mucus was found in the stomach; the villous coat was of a brownish-red colour, generally inflamed, and detached from the adjacent coat in places. None of the poison was detected in the stomach; but its nature was determined by the analysis of the portion left in the vessel from which it was taken. It is evident that the rapidity of the fatal result in this case was owing to the extent of the local injury, to the shock sustained by the constitution, and to the absorption, in a very short period, of so large a quantity of the salt into the circulation; this salt being rapidly absorbed, especially in solution, and acting not merely as an irritant, but also as a powerful sedative.

478. *c. Sulphate of potass*, according to Mr. MOWBRAY (*Med. Gaz.*, vol. xxxviii., p. 54), is much employed in France as a popular abortive, and when thus administered has proved not infrequently poisonous. It has also been employed in this country with the same object, and in one case, at least, with the same results, as shown by Mr. TAYLOR. In one case two drachms acted most powerfully, and in another four drachms, administered to a lady after her confinement, acted as an irritant poison. Another lady took, about a week after her delivery, about ten drachms of this salt, in divided doses, as an aperient. After the first dose she was seized with severe pain in the stomach, with nausea, vomiting, purging, and cramps in the extremities. These symptoms became augmented after each dose, and she died in two hours. On inspection, the villous surface of the stomach and intestines was found pale, except the valvulæ conniventes, which were reddened. The stomach contained much reddish liquid, which was found to contain only sulphate of potass.

479. *d. Oxalate of Potass.*—Salt of Sorrel.—*Bin-oxalate of potass* is an active poison, owing chiefly to the oxalic acid. It is much employed under the name of "essential salt of lemons," and instances of poisoning have occurred from its having been taken by mistake, some of which have been adduced by Mr. TAYLOR. The following case is recorded by Mr. JACKSON: A female, aged 20, took about an ounce of this salt in solution. About an hour and a half afterward she was found on the floor quite faint, having been very sick. The nature of the poison was soon ascertained, and four ounces of *mistura cretæ* were administered. She was then in a state of extreme depression; the pulse could hardly be felt; the skin was cold and clammy; the lips and face were pale, and rigours continually affected the whole body. She complained of a scalding sensation in the throat and stomach, of pain in the back, of soreness of the eyes and dimness of vision. The conjunctivæ were injected and the pupils dilated. She was wrapped in warm blankets; ether, tincture of opium and camphor were administered, and reaction took place. The patient afterward recovered. Most probably the greatest part of the salt had been thrown off the stomach before she was found. The treatment of this case throughout was as judicious as successful.—(*Med. Gaz.*, vol. xxvii., p. 480.)—A lady, recently confined, took by mistake an ounce of this salt. She had scarcely swallowed the dose when she was seized with violent pain in the abdomen and convulsions; she died in eight

minutes. The mucous membrane of the stomach and small intestines was found inflamed. A tea-spoonful of this salt was taken for three successive mornings, and produced severe vomiting; about an hour after the third dose the patient expired. There was no examination of the body. It is evident from these cases, that this salt is a powerful aro-sedative poison, its depressing operation being most energetic.

479\*. *c. Bi-tartrate of Potass.*—*Cream of tartar* is a most useful medicine, even in large doses; but it may be poisonous if a too large quantity be given. I have prescribed as much as two drachms three times in the day, in cases of dropsy connected with obstruction in the liver, with great benefit; but this dose should not be continued long, and its effects should always be carefully watched. Mr. TAYLOR states, on the authority of Mr. TYSON, that a man took four or five table-spoonfuls of cream of tartar, and was seized with violent vomiting and purging, with pain in the abdomen, thirst, feebleness of pulse, and a paralyzed state of the thighs and legs. The fluid vomited was of a dark-green colour, and the motions had the appearance of coffee-grounds. Death took place in forty-eight hours, and, on *inspection*, the villous coat of the stomach and duodenum was found highly inflamed; the cardiac portion of the stomach being of a deep-red colour, with spots of black extravasation. This organ contained a thick, brown fluid, coloured by bile. The intestinal canal was more or less inflamed.

480. *f. The nitrate of soda, the sulphate of magnesia, the bichlorate of soda, the chloride of sodium, and other salts, which are harmless in small or moderate quantities, are injurious, and act as irritants and depressants when taken in large or excessive doses, especially in states of disease or of constitution which are favourable to their injurious operation.*

481. vii. THE SULPHURETS OF POTASSIUM AND SODIUM.—*The alkaline sulphurets* have very rarely occasioned poisoning in this country; but they have caused fatal accidents in France, where they are frequently employed for baths and for the manufacture of artificial sulphureous waters. They act as powerful irritants of the digestive mucous surface and depressants of nervous and vital power, exhausting at the same time the irritability of contractile tissues. These latter effects are in great measure owing to their absorption into the circulation. M. ORFILA and M. CAYOL have recorded cases of poisoning by these sulphurets. The quantity taken in each of these was three drachms and upward. Two of the cases terminated fatally in less than *fifteen minutes*; the other patients who recovered were dangerously ill for some days. The rapidly fatal effects of these poisons were probably owing more to the change produced by them in the state of organic nervous influence, than to disorganization of the villous coat of the stomach.

482. *a. The symptoms* in these cases were burning pain and constriction in the throat, gullet, and stomach, frequent vomiting; at first sulphureous, the air of the chamber being tainted with the odour of sulphureted hydrogen, and afterward sanguinolent; purging, at first sulphureous, afterward mucous and bloody; sulphureous exhalations from the mouth; acrid

taste on the palate; pulse quick, afterward feeble, fluttering, and almost imperceptible; followed, in the cases which recovered, by inflammatory reaction of the digestive canal, extending to the œsophagus; and by mortal faintness and convulsions in the fatal cases.

483. *b. The structural changes* in the fatal instances were great lividity of the face and extremities, and loss of the muscular contractility immediately after death. The stomach was red internally, and lined with a crust of sulphur. The duodenum was also red. The lungs were soft, gorged with black fluid blood, and did not crepitate.

484. *c. The Treatment* seems to consist in the instant administration of any diluent at hand, and frequent doses of common salt. If inflammation of the stomach, &c., supervene, local and general antiphlogistic measures and external derivatives will be required. Dr. CHRISTISON observes, that the chloride of soda may be called the antidote against this poison, as it decomposes the sulphureted hydrogen which is evolved, the rapid disengagement of which he considers to be the cause of death in the quickly fatal cases. The chloride of lime is equally efficacious with the chloride of soda.

485. viii. TARTARIC ACID.—Oxalic acid in small doses, and tartaric acid in large quantities, are productive of nearly similar effects. *Tartaric acid* has, until lately, been regarded as not poisonous; but an instance lately occurred of this acid having been given to a man instead of aperient salts, in the dose of one ounce, with fatal effect. The whole of this was swallowed at once, dissolved in warm water. He immediately exclaimed that he was poisoned, complained of a burning pain in the throat and stomach, and compared the sensation to that of being all on fire. Soda and magnesia were administered with diluent drinks. Vomiting commenced, and continued until his death, which took place nine days afterward. Tartaric acid was found in the dregs of the cup, and the person who made the mistake admitted the act and the substance which he had thus given. On *inspection of the body*, nearly the whole of the alimentary canal was found inflamed. (See TAYLOR, in *Op. cit.*, p. 104.)

486. The *Treatment* of poisoning with this acid is the same as that for *oxalic acid* (§ 166), which, when given in smaller quantities than those usually productive of the corrosive action described above (§ 160, *et seq.*), is partially absorbed, and, with its local irritating operation, occasions also marked depressing and paralyzing effects; and either an acute, or sub-acute, or chronic form of poisoning, according to the quantity taken, the circumstances of the case, and the treatment employed soon after its ingestion. In the slower form of poisoning by *oxalic acid*, as well as that by *tartaric acid*, as soon as the poison is removed by vomiting or the stomach-pump, remedial measures should not be confined to the removal of the local irritation merely that is produced by it, but ought to be extended to the restoration of the nervous and vital powers, which are more or less depressed by the influence of the poison on the nerves of the alimentary canal, and, by absorption, upon the heart, nervous centres, and constitution generally; and with these intentions the means already recommended for the more

energetic aero-sedatives will be found the most successful for the removal of the consecutive effects, and for the slower forms of poisoning caused by small doses of oxalic acid, and by large quantities of tartaric acid.

487. ix. THE NECROSCOPIC POISON.—POISON IMBIBED FROM RECENTLY DEAD BODIES.—*A. Source and Nature of the Poison.*—The fluids of bodies recently dead, or that have not passed into an early stage of decomposition, not infrequently produce the most dangerous effects, especially when they come in contact with an abraded surface, or are inoculated in any way. The effects vary with the disease of which the person died, with the constitution of the infected individual, and with other circumstances. I have had several occasions of observing and treating the effects of this species of animal poison. Since I first published my views as to the nature and treatment of these effects, in 1823, and again in 1833, I have been more fully convinced of the accuracy of these views; and, moreover, they have received the support of experienced observers, and especially of Mr. TRAVERS, in more recent publications. The poisonous action of the fluids of dead bodies is most acutely exerted when these fluids are inoculated; but they sometimes act upon the perfectly sound skin, there being no scratch, puncture, or abrasion through which they could be introduced, the existence of either of these greatly facilitating and aggravating their operation. In the observations I offered respecting this poison (in the *London Medical Repository for July, 1823*), I stated, 1st. That this poison is distinct from any other animal poison, generated or transmitted during life; 2d. That it is different, in its nature and effects, from putrid animal matter; 3d. That it does not appear to exist in the blood, either during life or after death; 4th. That it is produced during the changes which are more immediately consequent upon the loss of life; and, 5th. That it is present chiefly in the secreted and exhaled fluids on the surface of membranes, especially serous membranes, or in cellular or parenchymatous parts. I then remarked that, as respects the distemper inoculated from another body which has recently ceased to live, and as regards the nature of the animal poison which causes the distemper, and the manner of its operation, it may be inferred that it is produced by the textures before their vital properties and cohesions are quite extinct, because putrid animal matters occasion different and less dangerous effects; that as all morbid poisons possess certain properties bestowed on them by the organic nervous or vital influence of the vessels and structures secreting them, in consequence of previous disease, either of these parts or of the frame generally, which properties they preserve for a time until the elementary particles composing them enter into different combinations, so may the secretions and fluid exhalations occasionally experience, during the period in which organic nervous influence and vitality are forsaking the tissues which secrete them, such a change as amounts to the acquisition of virulently poisonous properties, and that these fluids, thus changed, affect the nerves of the part to which they are applied, and, consecutively, the whole frame, the cellular tissue in the vicinity of the glands above the seat of inoculation generally evincing

more or less disorganization, and sometimes, also, the integuments, the fasciæ and tendinous sheaths, the absorbents, or veins, or both, and even the serous surfaces of adjoining cavities. This poison being productive of the most dangerous effects, and on numerous occasions, it is of the utmost importance, especially to medical men themselves, that its operation, and its counteraction and treatment, should be carefully investigated.

488. a. The poison communicated by recently dead bodies has been described, and illustrated by the details of cases, by Dr. DUNCAN, as constituting a form of diffusive inflammation of the cellular tissue, and by Mr. TRAVERS, as occasioning a variety of constitutional irritation. But the doctrine inferred from these denominations is too restricted to be applicable to the distemper which this poison develops. Diffusive inflammation of the cellular tissue certainly often exists as a consequence of the contamination produced by the poison; but it is preceded and attended by constitutional effects—by states of the circulation and nervous system—of the most malignant or virulent description. Constitutional irritation is equally present, and is certainly more or less immediately consequent upon the local irritation, impression, or alteration, or whatever the local effect may be; but so are depression of organic and cerebro-spinal nervous power, changes in the states of vascular action and of the blood, asthenic inflammation of the cellular tissue, and often, also, of the integuments, or of the absorbents or veins, or of adjoining serous surfaces. The truth is, that this poison produces an almost specific effect upon the tissues in the vicinity of glands above the seat of its application; but this effect may be limited to the cellular tissue, or extended to several other tissues; and it may be confined to the axilla, or extended to more deep-seated parts; it may not implicate, in a visible manner, any of the structures of the arm, although the poison was inoculated in the finger, and the cellular tissue in the axilla is most extensively diseased, no change between these situations being detected; and it may most virulently affect the nervous and vascular systems, and depress vital power and resistance, when the local changes are the least extensive or apparent.

489. b. It is of some moment to know the *diseases which impart this poisonous property* to the recently dead body; but, as to this, we have no precise information. Although the distemper which is the result has most frequently been produced by the inoculation of the fluids of bodies which had died of inflammations of serous surfaces, or of erysipelas, or of puerperal diseases, yet has it occurred also after the inoculation of the fluids of bodies which have died of other visceral or inflammatory maladies—of enteritis, peritonitis, &c. More than one person has even been infected by the same dead body, this occurrence evincing a greater virulence of the poison, in that body, owing either to the nature of the disease of which it died, or to the period after death at which the examination was made. That this has probably depended chiefly upon the former of these causes may be inferred from its frequent occurrence when the body has died of erysipelas, puerperal peritonitis, or other states of puerperal fever; while, on the other

hand, there is equal, if not stronger, reason to believe that the poison imbibed in dissection is not the result of diseased action, simple or specific, in the living subject, but is altogether generated immediately after death, although certain diseases may favor its generation at this period. That the poison is not the result of the disease of which the patient died, is shown by the facts, 1st. That this poison has been imbibed during the examination of bodies of persons who have died suddenly, and in health, in consequence of accidents; that poisonous effects have been produced by the fluids of a body which has been killed by an accident, or has died of a non-contagious disease; 2d. That the distemper developed by this poison presents a specific character, differing only in the degree of severity and the extent of the contingent local inflammation, whatever may have been the malady of which the subject which furnished the poison died. Still, the larger proportion of cases of this distemper have their origin from the fluids of bodies recently dead from inflammations, by which an abundant exudation of morbid fluids is accumulated, and in which the thoracic and abdominal viscera are examined and handled. In most instances which have fallen under my observation, the bodies from which the poison was imbibed were still warm when examined, and many of them had died of puerperal diseases. Mr. TRAVERS remarks, also, that the subjects were recent. Not one had been buried; some were yet warm. Even of those in which demonstration, not inspection, was the object, the bodies were in a perfectly fresh state; and he remarks a circumstance, which has also struck me, namely, that when the dissection has been performed before the body has entirely parted with its warmth, a faint and peculiarly oppressive odour is emitted, which is disagreeable, not to say revolting, even to persons habituated to dissection, and which not infrequently creates nausea.

490. *c.* The question may be asked, Whether or not the poisonous fluid may produce its effects when applied to the *perfectly whole cutaneous surface*, or only when this surface is punctured, or the cuticle abraded, in the part which comes in contact with it? I can answer this question in the affirmative from my own experience, and from statements made to me by others in the frequent habit of making inspections. I have seen severe constitutional disorder of the specific kind produced by this poison in two instances, in which the subjects had died of puerperal disease, the surgeons who assisted me in the examinations, and who thus imbibed the poison, having had no abrasion of the cuticle whatever. The fluids accumulated in the serous cavities occasioned, in these two instances, a sensible smarting over the surfaces with which they remained for a time in contact. But I believe that such instances are rare compared with those which are owing to some scratch, abrasion, or puncture of the cuticle.\*

491. *d.* Another question suggests itself, namely, *Whether or no this poison is the same as the infectious emanation which caused the disease of which the person died; is allied to a specific contagion existing still in the body which has died in consequence of it?* We know that the poison under consideration is frequently imbibed from bodies which have died from puerperal diseases, from visceral inflammations, from erysipelas and other maladies. But the distemper produced by this poison is not in any respect the same as any of these diseases, there being no farther resemblance than in the febrile disturbance present in all of them, and in the vital depression and weak state of vital resistance. That small-pox, syphilis, erysipelas, glanders, and even scarlet fever may be transmitted by the recently dead body; and that the power of transmitting these specific contagions may be retained by the bodies which have died of them for a considerable but an indefinite time, I believe; but when the body is surrounded by clothes of any kind, this power of transmission is retained by the clothes rather than by the body itself; for, as soon as the latter undergoes decomposition, the power of transmitting the specific malady which caused death appears to have ceased, especially if there be a free admission of atmospheric air, because the contagious secretions are also decomposed, and, by their decomposition, have lost their specific and poisonous properties. It cannot, however, be inferred that the distemper produced by the poison imbibed from recently dead bodies is allied to any of the maladies which has most frequently caused the deaths of the bodies from which the poison was imbibed.

492. *B. Symptoms.*—(*a*) In some cases, the following is the usual procession of morbid phenomena. 1. A few hours after puncturing a

the finger up the arm, along the neck, to the tip of the ear. Matter formed within the proper sheath of the flexor tendon of the finger, and the wound in the finger continued to discharge freely after the sheath was laid open. Delirium, rapid pulse, &c., continued, and was followed by rigours and profuse colligative sweating, and soon afterward by extreme depression, and death. 2d Case. The maid-servant who fomented this woman's hand, on the third day after the incision of the finger, complained of pain and tension of the point of the fore-finger of the right hand, with constitutional disturbance and delirium. She had neither wound nor seration of any kind. Acute fascial inflammation of all the fingers, back of the hand and fore-arm, followed, and abscesses formed, requiring free incisions. 3d Case. A laundress, who washed the sheets taken from the bed of the first of these patients shortly before her death, "had no sooner opened and immersed them in water, than she was overpowered by an effluvia, which she described as peculiarly offensive, and instantly complained of a most severe darting pain in the axilla and shoulder. Nausea and faintness followed, and in the evening she had a rigour which lasted three hours. In the morning she was much fevered, and on the two succeeding nights violently delirious. The pain she now complained of affected the outer side of the upper arm, from the elbow to the shoulder, but there was neither redness nor swelling of this part." Afterward the pain shifted in the axilla and pectoral region, and two days afterward a deep pectoral abscess presented itself. She ultimately recovered. In neither of the second or third cases was there any breach of the cuticle, by which absorption of, or contamination by, a poisonous fluid could be facilitated. Mr. TRAVERS adds, that the laundress was attacked at the one and the same instant with nausea and faintness from the stench, and with acute lancinating pain from handling the linen; and that a woman who was present informed him that the laundress turned as pale as death, and exclaimed with agony, from the pain she felt in the arm within two minutes of unfolding the sheets. I quite agree with this very able surgeon in remarking that this was surely the operation of a subtle poison on the nervous system, as it is only through this medium that it could operate so instantaneously.

\* The following cases, abridged from Mr. TRAVERS'S work, are remarkable, as they are examples of a distemper, in the local and constitutional symptoms, closely akin to, if not actually identical with, that produced by the poison imbibed from recently dead bodies, although the poison, in the second and third cases, was imbibed from the secretions of the first case while she still lived. 1st Case. A female, while suckling, had a poisoned wound of the finger, followed by pain, fever, and delirium. The pain extended from

finger in the examination of a body, pain is felt in the puncture. It soon increases to the utmost agony, and is attended by symptoms of constitutional irritation, the nervous system being agitated to a violent degree. No trace of inflammation beyond slight redness of the puncture is observable; and no evidence of inflammation of the absorbents or veins can be detected. In a case recorded by Mr. TRAVERS, death took place forty hours after the puncture was received, with all the symptoms of agonizing excitation of the nervous system, the distemper resembling hydrophobia. 2. In other cases, the puncture is also not attended by any evidence of inflammation, but, in ten or twelve hours afterward, feelings of indisposition are complained of; violent rigours are soon experienced, followed by febrile reaction, nausea, or vomiting, and most rapid pulse. Severe pain is felt about the shoulder, axilla, or pectoral muscle; but no trace of inflammation can be detected between the puncture, generally of a finger, and the seat of pain. Anxiety, depression of spirits, delirium, profuse perspiration, singultus, most rapid and small pulse, insensibility, and death supervene. 3. In some instances, from ten or twelve to twenty-four hours after the imbibition of the poison, languor, depression, shivering, and sickness at stomach are experienced; a *vesicle*, or *pustule* resembling that of smallpox, is observed in the punctured or abraded part, and pain is felt in the shoulder or axilla, or both, but without any sign of inflammation of the lymphatics, or of any other tissue of the arm. The pain extends to the breast of the same side, and is attended by nervous excitement, thirst, watchfulness, headache, a hot and dry skin, a frequent and weak pulse, afterward by delirium, irritability of stomach, by swelling or redness about the axilla or pectoral muscle, by sinking of the powers of life, and often by death. 4. In other cases, no vesicle or pustule forms in the seat of puncture, but severe constitutional symptoms are rapidly developed; the pulse in a day or two rises to 120 or 130; delirium soon appears; slight swelling and excruciating pain affect the axilla and breast, attended by diffuse swelling, patches of colour, and severe pain in different and distant parts of the body, by nausea and vomiting, by singultus, and sometimes by yellowness of the conjunctiva and skin; followed by a weak, small, and rapid pulse, exhaustion, laborious breathing, and death. 5. In all the preceding *phases* of this distressing distemper, the puncture or abrasion by which the poison was imbibed, and the tissues in the vicinity, have presented no alteration, excepting the superficial vesicle or pustule observed in some instances, and no local lesion or disorganization appears until after the constitutional symptoms have been fully developed, and then it takes place near or on the trunk, in the situations already mentioned. But, in another class of cases, the wound or puncture of the finger suppurates, not, however, until after severe constitutional symptoms have appeared, especially rigours, vomitings, pain in the axilla or shoulder, very rapid pulse, physical and mental depression, with white or loaded tongue, dry and hot skin, &c. The puncture or abrasion now begins to suppurate, and swelling extends along the finger and sometimes over the hand. Sphe-

lation of the cellular tissue, and often also of the tendinous structures, takes place; the pain in the axilla or shoulder is followed by diffused and slightly coloured swelling, extending sometimes to the integuments of the same side of the body. As the disease continues, headache, watchfulness, delirium, irritability of stomach, thirst, and singultus vary in severity; and, if no alleviation take place, these symptoms increase; the physical and mental exhaustion are extreme; restlessness, followed by insensibility and coma, appears, and death takes place after periods varying from four or five to twelve or fourteen days. 6. In other cases, a diffused swelling, tension, and redness affect the wounded finger, subsequently to the occurrence of severe rigours, prostration of strength, frequency of pulse, and other constitutional symptoms. The swelling, tension, and redness extend to the hand, or up the arm, upon which numerous vesicles form, followed by tumefaction, and insulated patches of colour on the shoulder, breast, and back, on the same side of the body. The febrile and the nervous symptoms continue to increase with the development of local lesions; and the pulse, strength, and constitutional powers generally become weaker, death taking place in the majority of cases after periods varying as just stated. 7. In some instances, after the appearance of rigour, fever, nervous and other general symptoms, the axilla becomes painful and swollen. Diffusive inflammation proceeds extensively from this part through the cellular tissue, extending in some cases to both sides, and suppurates or sloughs; inflammation of, and effusion into the pleura, often ultimately supervening. Death generally takes place in these cases with the usual symptoms, and after the indefinite period already mentioned.

493. From the above brief account of the several *phases* of this dreadful distemper, it may be inferred that the local inflammatory action is an unessential and subordinate feature of the disease in its severest forms; that the distemper actually consists of prostration of the nervous influence and vital energy generally, the local irritation arising from the impression or imbibition of the poison occasioning slight change of structure in some instances, and more extensive inflammation and disorganization in others, as already noticed, and as will be more fully described; and that the contamination produced by this poison is characterized by preternatural excitement of the nervous and vascular systems, without power or vital resistance, that soon passes into rapid exhaustion. A circumstance deserving of notice in this distemper is the remoteness of the local inflammation, in the great majority of instances, and in all its above phases, excepting the sixth, from the part at which the poison is imbibed; and the absence of any sign of inflammation of the absorbents or veins in a great proportion of the cases between the seat of injury and that of pain and inflammation. But this phenomenon is also remarked in other maladies produced by a specific animal poison, as syphilis. It would appear that this poison, whether conveyed by the absorbents or by the nerves, especially those supplying the blood-vessels, affects the glands of the axilla, and probably also the axillary plexuses of nerves, in an especial man-

ner, and that the surrounding cellular tissue becomes asthenically or diffusively inflamed in consequence, and the consecutive lesions are thereby produced.

494. *C. Prognosis.*—Much depends upon the severity of the constitutional symptoms at an early period of the distemper, and upon the treatment then adopted. Those cases in which the local affection is the least severe, and the nervous and febrile symptoms most prominent, are the most dangerous; and, if the disease be not arrested at an early stage by most decided means, these symptoms, and with them the local inflammation, rapidly increase and pass beyond the influence of any remedial means whatever.—*a.* The prognosis is generally most *unfavourable* when the irritability of the stomach extends to the diaphragm and is attended by hicough; when the tongue becomes brown or dry, or both; when the pulse rises above 120 in a minute, and is weak or small; when anxiety and mental depression are great, the features sunk, or the extremities cold; when a lurid, dirty, cachectic, or yellowish hue of the countenance and general surface is observed, and more especially early in the distemper; when the individual has been previously out of health, is cachectic, or the subject of disease of the heart, or of a varicose state of the veins; and when delirium becomes continued, and is attended by unconscious evacuations. In these circumstances few or no hopes of recovery may be entertained; but, nevertheless, active measures, such as I shall recommend, should not be relinquished. If these symptoms be accompanied with signs of extensive local disorganization, the chances of recovery are diminished, owing to the probable absorption of morbid matter into the circulation. Still, energetic measures should be prescribed; but, unless these measures are of a powerfully restorative kind, they will be productive of no benefit, especially if hicough be present; and even when most restorative, they may fail, or may not be retained on the stomach, particularly at a far advanced stage of the distemper.

495. *b.* A more *favourable* result may be anticipated if the pain is less violent, if the pulse becomes less frequent, and the delirium is only present at night. If sleep be obtained, if the tongue continue moist, if singultus be not present, and if medicines be retained on the stomach, more sanguine hopes of recovery may be entertained. As respects the local affection, much will depend upon the rapidity and extent of its progress under the integuments and muscles of the affected side; and the amount of ease obtained from incisions, and the discharge of purulent matter. If the discharge be followed by a limitation of mischief or disorganization, and if the inflammation of the deep-seated cellular tissue has not implicated the pleura, it may be hoped that such measures as assist vital resistance may still prove successful, not only by arresting, but also by remedying the already existing disorganization. Of eight cases which I have seen of this distemper, seven recovered; but all these came under my care at an early period. The fatal case occurred in a gentleman who was the subject of varicose veins, and was otherwise cachectic. I saw him shortly before his death, which took place after a short period from the imbibition of the poison

during the examination of a recently dead subject; the local symptoms in his case having been slight, but the nervous and constitutional disturbance most severe and rapidly fatal.

496. *D. Appearances after Death.*—These have been but imperfectly described, and comparatively few of the fatal cases have been examined. The lesions observed are, 1st. Those which are found in the external parts of the body; and, 2d. Those which are detected in the cavities and in the viscera.—(*a*) In the former, the changes are in some instances very slight, or hardly appreciable, unless in the vicinity of the axillary glands, in others most extensive. These changes may consist of serous infiltration of the cellular tissue surrounding these glands, which are generally more or less enlarged or inflamed, or both, or of a sero-puriform, or puriform infiltration, with or without destruction of the cellular tissue itself, as described in the article on diffusive inflammation of the CELLULAR TISSUE (§ 20, *et seq.*). In some instances the disorganization proceeds so far between the pectoral and respiratory muscles as to implicate the pleura, the external surface of the *costal-pleura* being also inflamed. The *muscles* themselves are sometimes changed, especially in the vicinity of the sphacelated cellular tissue or of the collections of puriform matter; the muscular fibres being of a dirty yellow colour, and devoid of cohesion. The *veins* are sometimes implicated, but seldom to a great extent, unless those which pass through the inflamed and disorganized cellular tissue. The *absorbents* between the puncture and the axillary glands sometimes betray no change, neither the superficial nor the deep-seated. In some instances, these vessels appear thickened or enlarged, and are, in various places, surrounded by sero-puriform, or puriform collections, in small quantities, in the cellular tissue. The *arteries* of the limb are rarely altered, excepting the smaller branches, which either supply the disorganized cellular tissue, or which traverse it. The state of the *nerves* has not been accurately observed, or has been reported as not materially changed; but in one or two instances the nerves of the arm, especially the internal cutaneous nerve, have been found inflamed. The *aponeuroses*, the *fascia*, the *theae*, and the *tendons* have sometimes been found inflamed, or surrounded by, or covering, or containing puriform matter or pure pus. Lesions of one or more of these structures are chiefly seen in those cases which are noticed as constituting the fourth, fifth, sixth, and seventh phases of the distemper (§ 492); in many of those cases, which are ranked under the first, second, and third phases, these lesions, excepting those of the cellular tissue and axillary glands, are either wanting, or so slight as not to be remarked. The lesions of these several tissues are generally most remarkable when the limb and external parts in the vicinity of the axilla present the more evident signs of disease or disorganization; and the symptoms during life vary with the texture more especially implicated, as shown in the articles upon the diseases of these textures. In the majority of cases, and more especially when the poison has been imbibed from a very recent or warm subject, no alteration can be traced after death in the arm, or any connexion between the abrasion or punc-

ture of the finger and the changes existing in the vicinity of the axilla and pectoral muscles, more than could be observed during life.

497. (b) If the external alterations have been but superficially observed, the visceral changes consequent upon this poison have been still more imperfectly described, if, indeed, described at all. The most prominent lesions have been observed in the *pleura*, particularly in that of the affected side, when the diffuse inflammation of the cellular tissue and its consequences have extended to the *pleura*. In these cases the *pleura* is inflamed, generally throughout that side of the thorax, and the cavity contains a turbid serum, or a large quantity of bloody serum, with flakes of lymph floating in it. The inflammation extends from the costal to the diaphragmatic and the mediastinal *pleura*, and even to the pericardium, the pulmonary *pleura* being also inflamed. The *lungs* are rarely affected, but they have been found more or less congested. The *heart* has been seen somewhat flabby, and its right side and *vena cava* have presented inflammatory appearances. The stomach, intestines, liver, &c., are generally represented as natural, and the brain, spinal cord, and their membranes either have not been examined, or they are said to have been unaltered.

498. *E. Causes predisposing to Infection by this Poison.*—There are manifestly circumstances which predispose to the infection of this poison, and increase the virulence of the distemper produced by it. Attention to these causes may aid in preventing, or even in counteracting its effects. The operation of this, as well as of all animal poisons, is favoured by whatever lowers the powers of life or weakens the vital resistance to injurious agents; by the depressing emotions, by fear especially, by disordered states of the digestive organs, or by accumulations of secretions and fecal matters in the digestive canal; by a languid, impoverished, or an impure state of the circulating fluids; by general cachexia or anæmia; by fatigue, want of sleep, or exhaustion of nervous energy; by excesses of all kinds; and by an irritable and susceptible state of the nervous system. Probably also idiosyncrasy, the nervous and irritable temperaments, a debilitated state of the frame, or natural delicacy of constitution or conformation, favour the morbid impression of this poison, and impart a greater intensity to its effects. My experience has shown that these circumstances are influential in the way now stated; while their opposites are equally influential in resisting the operation of the poison, or in rendering the effects less dangerous.

499. *F. Nature of the Distemper.*—The constitutional symptoms are generally the same in all cases of this terrible malady, and differ merely in severity and the rapidity of their course. They always precede the more prominent local alterations, but become more severe with the progress of these. In addition to several other phenomena characteristic of this distemper, it is generally observed, in the more prolonged cases, that, previously to a termination in death or recovery, swelling and inflammation affect a portion of the limb interposed between the original wound and the first seat of pain. The swollen parts present a redness very unlike that of erysipelas; for the tint is that of peach-blossom, and is very small in ex-

tent compared with the extent of the swelling, and is seen for a very short time, perhaps for a few hours only, never longer than a few days, on the same spot, and next is observed in some distant part, possibly even on the opposite limb. Besides, this peculiar redness, vanishing quickly from a part, does not leave any vesication or desquamation after it, as is seen in cases of erysipelas. When the swollen parts are incised they yield only a small quantity of blood, or serum and blood, unless the incisions are delayed until the effused fluid assumes a puriform character. On this topic Dr. COLLES remarks, that this peculiar disease, the effect of slight wounds received in dissection, presents much less of inflammation of the wound or its vicinity than occurs in the various diseases to which slight injuries more frequently give rise. Here the injury seems to produce mischief by exciting a fever, which in its turn induces a swelling and redness of very peculiar character, although at length (if the patient chance to survive) it will end in inflammation and suppuration of the wounded limb. (*Dub. Hosp. Rep.*, vol. iv., p. 247.)

500. Having seen the inoculation of this poison so frequently during examinations of puerperal subjects, and of persons who had died of erysipelas, the question suggested itself: Can the distemper which results be merely a form of erysipelas produced by inoculation? But this idea was met by the fact that it has been caused by wounds or abrasions received in the examination of recent subjects, irrespective of the disease which produced death, although my experience has shown that these maladies, and inflammations of serous membranes attended by fluid effusion, have most frequently occasioned it. There still remains much to be ascertained respecting it, before accurate views as to its nature can be entertained; for the changes produced in the nervous systems and centres, the appearances of the blood, both during life and after death, and the possibility of propagating a similar distemper by the serous fluids of the body of one who has died of it, or by the secretions during life, have not been investigated. Strongly impressed with the imperfect state of our knowledge of the pathology of this distemper, owing chiefly to the very superficial examinations of the bodies of those who have died of it, and to the general adoption of a very injurious practice in the treatment of it—a practice which has proved unsuccessful in the great majority of cases for which it has been prescribed, and which is yet persisted in with little variation, I would, nevertheless, suggest the following views as to its nature, especially as they have been the basis on which I laid my indications of cure in the cases which were treated successfully.

501. *a.* The poison communicated by, or imbibed from, a recently dead human body is of a specific nature, and produces a specific malady; specific, more especially, as respects the constitutional symptoms, and peculiar, as just shown, as regards the consecutive pain and inflammation in the axilla, arm, and side.

502. *b.* This poison is connected with the secreted and exhaled fluids before they have undergone any change or decomposition, and before any of the properties imparted to them during life, or during the departing vitality of

the frame, has escaped from them; the loss during decomposition of properties derived from, or depending upon the state of vitality, rendering them inert. In these respects, as regards the source of morbid properties, and the loss of those properties, the fluids producing this peculiar malady in every respect resemble the fluids infecting small-pox, measles, scarlet fever, &c.; are identical with the infection of the exanthemata; decomposition or putrefaction destroying, while recent production increases, the poisonous properties.

503. *c.* There is every reason to infer, from facts already before the profession, that this poison exists, probably in various and varying grades of activity, in the serous and exhaled fluids of all human bodies recently dead, whether from accident or disease, and irrespective of the nature of the disease; but that certain maladies, especially those in which the serous membranes and the circulating fluids are most liable to be especially affected, as puerperal diseases, erysipelas, peritonitis, &c., appear, in the present state of our knowledge, to cause this distemper the most frequently.

504. *d.* We do not possess evidence of this infection being communicated by a person labouring under the effects of poison—by a living person;\* and this may arise from the circumstance of the fluids which are more especially or specifically infectious or poisonous being those which exist in shut or serous cavities or in viscera, and which cannot hence be imbibed during life; although other fluids, exhalations or secretions, which are probably less poisonous or infectious, may communicate a modified or less virulent malady, as, indeed, seems to have been the case on some occasions, as noticed below.

505. *e.* The morbid impression made by the poisonous fluid imbibed from a recent subject, seems primarily to affect the nerves of sensation in connexion with those of organic life;

\*Dr. NELSON states, in his account of the illness of Mr. NEWBY, who died from the effects of this poison, that Mr. N.'s assistant had an erysipelatous inflammation of the fauces, and the pupil an attack of low fever, during the latter part of Mr. NEWBY'S illness; that the housemaid was severely affected with cyanicæ tonsillaris; that the nurse had a slight attack of pyrexia, with pain and stiffness at the back of the neck, followed by erysipelas, which proved fatal; and that another who assisted just after Mr. N.'s death had also erysipelas, but recovered. Dr. NELSON adds, "Was the disease which destroyed Mr. N. erysipelas produced by inoculation and affecting the cellular substance of the breast and parts adjoining? Did the five cases which occurred during his disease and after his death arise from erysipelatous contagion?" (*Medical and Phys. Journ.*, Aug., 1823.)

Mr. DELPH, surgeon, imbibed this poison from a woman who had died a few hours previously of visceral inflammation, the body being still warm when it was examined. The woman who nursed this person and washed the linen was seized with fever. Mr. SMART, who assisted Mr. DELPH in this examination, was also attacked with symptoms of low fever on the second day afterward, and with numbness and inability to move the right arm. The side became tender and swollen; the fever typhoid, and the sensorium much affected. During the early part of Mr. SMART'S illness he was taken care of by a servant who happened to wound the index finger of the right hand. The wound became inflamed, swollen, and livid; and although early opened, much pus was discharged, and the extensor tendon had suffered. A tumour soon afterward formed in the axilla, which was also opened. This man was removed to his father's house, and was nursed by his mother, who had an attack soon afterward of inflammation of the hand, with much fever. In none of the above cases "were the absorbents of the arm inflamed, showing the red line which usually marks the track of the mischief from the punctured part into the system." (TRAVERS, *Op. cit.*, p. 327.)

and, as these nerves are intimately associated with the vessels and absorbents of the limb, on the one hand, and with the ganglial system on the other, the morbid impression or irritation produced by the poison is followed by a general disturbance or tumult of all the functions actuated by the ganglial or the organic nervous system; by excessive vascular action, without nervous energy or vital resistance, these states passing into exhaustion, with sinking of vital power, and contamination of the circulating fluids.

506. *f.* The primary impression of this poison is not only irritating, and productive of exquisite pain, in many instances, and of inordinate excitement in most, but it is also of a depressing nature, inasmuch as it often is followed by a numbness in the vicinity of the puncture, or by aching, or feebleness of the limb; the local change thus primarily produced being probably a chief cause of the consecutive changes which take place, especially after the frame is infected, in the glands and other structures in the axilla and its vicinity of the inoculated side.

507. *g.* The constitutional commotion, generally developed from ten to twenty hours after the imbibition of the poison, is displayed by all the organs actuated by the ganglial system, and by the brain; both the organic and the cerebro-spinal nervous systems evince much disorder, and this disorder is characterized by altered or excited sensibility, and by deficient energy; the functions of vital organs being co-ordinately affected, vascular action remarkably excited, and the blood, and all the secretions from it, ultimately more or less altered, as in malignant distempers.

508. *h.* The nature of the constitutional commotion, of the vascular excitement in this malady, has been misunderstood by most practitioners and writers, and the character of the pulse misinterpreted; and, because there have been very acute pain, and remarkable frequency of pulse, often with delirium, many have most unwarrantably inferred the existence of sthenic or true inflammatory action, instead of its opposite, and had recourse to large vascular depletions, which have aggravated the pain, increased the frequency and weakness of the pulse, and induced or rendered more severe and continued the delirium. Oh! that ignorance would be less presuming, and not actually inflict the death it is blindly attempting to prevent.

509. *i.* The state of predisposition of the poisoned person, depending upon temperament, constitution, and the existing health, is most probably influential in developing the primary impression and the consecutive effects, or in aggravating their severity. This has been proved by cases which have come under my own observation, where surgeons, who have aided me in the inspection of very recent bodies, have, without any wound or abrasion of the cuticle, or after such injury, complained only of comparatively slight constitutional symptoms, which yielded to treatment, without the local symptoms having appeared.

510. *k.* In most cases no morbid connexion can be traced between the puncture, or the point of inoculation, and the subsequent alterations which take place in the axilla and vicinity: no change is observed in any of the tissues

between this situation and the puncture or scratch in the finger or hand; unless the change exist in some of the nervous fibres, and be of such a nature as not to admit of recognition by the unaided senses. The constitutional commotion is generally ushered in by altered sensibility of the poisoned part and of the arm, but is unattended by any visible change, although in some cases the absorbents, either superficial or deep-seated, appear to be affected, and is characterized by its early appearance, and by remarkable physical and moral depression and anxiety, followed by rigours, which are succeeded by reaction and excessive nervous and vascular excitement, devoid of energy or vital power. The alterations which occur in the axilla and vicinity never commence until the constitutional disturbance is produced, generally after the rigours and consequent reaction, and are preceded by exquisite pain, often extending to the shoulder and arm.

511. *I.* The inflammatory changes in the axilla and vicinity do not take place in some of the most violent and dangerous cases; the poison, apparently, not being intercepted by the glands, and affecting chiefly the nerves and exerting its noxious influence upon the nervous systems and constitution generally.\* These changes are merely contingent upon the majority of cases, and do not constitute the disease; the constitutional affection not only preceding them, but being also over-proportioned to them. They are, moreover, in some instances, entirely absent, as in the first phases above specified (§ 492). I therefore agree with Mr. TRAVERS in stating "that the local inflammatory action is an unessential and subordinate feature of the malady in its severest form; the disease itself consisting in a direct prostration of the vital forces, marked by preternatural excitement and rapid exhaustion."

512. *G. Treatment.*—It has been justly remarked by Dr. COLLES that, "whatever difference of opinion may be entertained as to the nature of this affection, it will be allowed that, although some few have escaped, yet the plans of treatment hitherto pursued have all proved quite unequal to contend with so formidable a disease." But the plan which he proceeds to advise has nothing to recommend it in preference to those which have been previously adopt-

ed, if, indeed, any definite or rational plan had ever been prescribed. The means which had usually been employed consisted of blood-letting, general and local, opiates, fomentations, purgatives, &c.: the blood-letting having been prescribed for the insufficient reasons that the pulse was rapid, and the febrile symptoms and delirium excessive: reasons more correctly indicating the propriety of adopting very different measures. Dr. COLLES, knowing that this treatment was most frequently followed by an aggravation of the malady, simply advises calomel in doses of three grains every three or four hours, with the intention of quickly exciting pyalism. But, despite of the magic number three, he might consider himself most fortunate if he succeed at all in this intention, and "fortunate beyond compare" if he succeed either quickly or with a perfectly favorable issue.

513. The virulent poison imbibed from a recently dead body invades the healthy frame with a rapidity and intensity proportionate to the deficiency of vital power opposing the invasion; and whatever means are administered to the person infected by this poison, calculated to lower vital power and resistance, will only aggravate the effects by accelerating the absorption, and facilitating the operation of it upon the frame. All animal poisons exert more or less of an asthenic influence upon the healthy body—an influence which is not only morbid, not merely an alteration from the healthy condition, but also one of depression, a condition characterized by an imperfect as well as altered manifestation of the functions of life, and tending to the extinction of those functions. But when this primary effect is not so intense, relatively to the powers of life, as to overwhelm these powers altogether, they react against it, oppose it, resist its extension, and often completely overcome it. In many instances the impression made by the poison on the nervous system, and the contamination induced in the circulating fluids, lead to a violent struggle between these changes and the powers which resist them; the struggle ultimately terminating either in the removal of these changes or in the annihilation of the powers which have opposed them. Now, if I have observed and interpreted aright the phenomena produced by the poison in question, this is what actually occurs after the imbibition of it by the healthy frame: *first*, asthenic and morbid action; *secondly*, vascular excitement, the morbid influence on the nervous and vital powers still continuing; and, *thirdly*, disorganization and death, which are rapid in proportion to the invasion of the cause, and the failure of the vital powers of resistance. If it were asked, What are the measures which are most likely to increase not only the first and third of these effects, but also the second? I could not hesitate to answer, those very measures which have been hitherto too generally adopted to remove them. It may, however, be contended that the reaction which supervenes requires to be moderated by blood-letting in order to prevent its exhaustion; but I have shown that the reaction is most morbid—is a tumultuous excitement, deficient of power or constitutional resistance; that the pulse is that of irritation—of what JOHN HUNTER would call constitutional alarm; that the blood is not inflammatory, and the coagulum is not firm; and,

\* The following case illustrates this rapid and violent form of the malady: Mr. E., medical student, punctured his finger in opening a body recently dead. This occurred at noon (of Monday), and in the evening of the same day he found the wound painful. During the night the pain increased, and symptoms of high constitutional irritation were present on Tuesday morning. No trace of inflammation, however, was apparent beyond a slight redness of the spot at which the wound was inflicted, which was a mere puncture. In the evening he was visited by several physicians, but no local change could be discovered. The nervous system was agitated in a most violent and alarming degree, the symptoms nearly resembling the universal excitation of hydrophobia; and in this state he expired at three o'clock on Wednesday morning, forty hours from the injury. (TRAVERS on *Const. Irritation*, p. 262.) This case, and other instances of a less violent character, seem conclusive of one of two things, namely, either that the poison acts upon and affects the constitution through the medium of the organic nervous system, or that it is absorbed into the circulation in some cases without inflaming the absorbents or glands, or veins, occasioning the most severe effects upon the nervous system and vital energy, although inflammation of these structures, more especially of the glands and the surrounding cellular tissue, is often produced in consequence of the affection of the nervous system, or of the absorption, or of both.

moreover, that the rapidity of the pulse, and the severity of the delirium, and all the other symptoms are aggravated by this measure; and are of such character, and are attended by such phenomena, as ought to suggest a very different method of cure.

515. When treating of *diffusive inflammation* of the CELLULAR TISSUE, I pointed out the means which should be employed, both as *prophylactic* and *curative*, in the treatment of this disease when connected with, or consequent upon, poisoned wounds. Since that article was written, my farther experience has proved the correctness of my views, in respect both of the prevention and cure of the effects arising from the poison imbibed in the dissection of recently dead bodies, as stated in that article (§ 34, *et seq.*); and, therefore, I now more strenuously advise the adoption of the principles and means of treatment there recommended.

516. *a.* The *prophylactic* means should be promptly applied, and should consist chiefly of a *ligature* applied above the puncture, scratch, or abrasion, when the situation of either admits of its application, or a cupping-glass, or even a common wine or ale glass, may be applied in other circumstances, the air being excluded in the usual way, or suction or pressure may be employed: afterward the wound should be carefully washed, and a pledgit of lint, wet with spirits of turpentine, placed over it. This application I have found more efficacious than any other, and it is not productive of any local irritation. When these measures have not been taken, or not taken sufficiently soon, the part wounded should be viewed as still containing a portion of the poison, and be subjected to them, although several, or even many, hours may have elapsed; and the constitutional powers ought to be fortified by means of pure air and generous living.

517. If *constitutional disturbance* should appear notwithstanding, or if it have already appeared owing to a neglect of prophylactic treatment, it should be promptly met by stimulating diaphoretics conjoined with tonics; and by warm or stomachic aperients, conformably with the principles maintained when discussing the treatment of *diffusive inflammation* of the *cellular tissue* (§ 34, *et seq.*) and of the *lymphatics* (§ 17, *et seq.*). The decoction of cinchona, therefore, should be given with liquor ammoniæ acetatis and full doses of the sesqui-carbonate of ammonia; and the bowels evacuated by means of a draught with equal parts of the spirits of turpentine and castor oil, and of an enema, containing the same substances, with or without ten grains of camphor. These may be subsequently repeated, according to circumstances.

518. *b.* The chief intentions of cure are, *first*, to prevent infection; *secondly*, to resist the extension of the mischief if infection have actually taken place; and, *thirdly*, to relieve the urgent symptoms, both constitutional and local, which usually appear when the disease is fully and unfavourably developed. The *first* of these having been premised, the *second* should be energetically employed, notwithstanding the tumultuous state of the vascular excitement or the delirium which may be present. The medicines just recommended ought to be early prescribed, and the dose of the ammonia suited to its effects. Instead of the combination of the

cinchona now mentioned, the decoction may be given with the chlorate of potass and the hydrochloric ether; and either of these combinations may be aided by the addition of camphor, by warm aromatics, by spices, &c., more especially by capsicum, which often prevents or alleviates the sickness and irritability of the stomach, and even the singultus of a more advanced stage of the distemper. If these do not relieve the disorder of the stomach, creasote should be given with camphor, capsicum, and small doses of opium, these medicines being generally indicated, when restlessness, watchfulness, or delirium supervenes. When, however, this last symptom appears, the doses of these substances ought then to be increased, and the morphia substituted for the pure opium or its tincture; full doses of these being given shortly before bedtime. Morphia or opium, or such of the preparations of opium as may be prescribed for the nervous symptoms of this malady, should be given in a very full dose, and conjoined with camphor or with capsicum or other warm spices, a full dose being given in the evening, and a smaller one in the morning. The infusion or decoction of cinchona may be also conjoined with other medicines, as the bicarbonate of potash, or soda, or ammonia, and be taken in a state of effervescence with citric acid or lemon juice; but the carbonate should be in excess, and the warm spices or aromatic tinctures be added. In the advanced stages of this malady, and for the local lesions which supervene in the course of it, the treatment should in all respects be such as already advised in the article on *diffusive inflammation* of the CELLULAR TISSUE (§ 34, *et seq.*).

519. *x.* PUTRID ANIMAL MATTER is productive of injurious effects when taken into the stomach; but these effects are much more serious when such matter is applied to an abraded surface, or to a wound, and more especially if it be injected into a vein.—*A.* As to the *ingestion* of this matter, Dr. CHRISTISON well observes, that “to those who are not accustomed to the use of tainted meat, the mere commencement of decay is sufficient to render meat insupportable and noxious. Game only decayed enough to please the palate of the epicure has caused severe cholera in persons not accustomed to eat it in that state. The power of habit in reconciling the stomach to the digestion of decayed meat is inconceivable. Some epicures in civilized countries prefer a slight taint even in their beef and mutton; and there are tribes of savages who eat with impunity rancid oil, putrid blubber, and stinking offal. How far putrefaction may be allowed to advance without overpowering the preservative tendency of habit, it is not easy to tell.” Something, however, is due to the nature of the beverages taken along with the articles in this state, and to the powers of digestion and assimilation possessed by those who partake of such food, in enabling them to resist the injurious effects produced by it in others.

520. *B.* The *exhalations* produced by putrid or decaying animal matter have generally been viewed as most noxious, until Dr. BANCROFT, the apostle of modern non-infection, endeavoured to prove, in a most ponderous volume, their very harmless nature. The present state of information, and the good sense, not only of

medical men, but of all competent observers, have completely disproved this absurd and injurious opinion. These exhalations are generally more or less noxious, especially when inhaled into the lungs for some time, or in certain states of predisposition to be infected by them, or in grades of considerable concentration, or when dissolved in the humidity of the atmosphere. M. MAGENDIE demonstrated that dogs confined over vessels in which animal matter was decaying experienced similar effects to those observed in the experiments performed by him and M. GASPARD upon the introduction of putrid animal matter into the veins. These effects resembled in every respect the *putrid form of fever* described in the article FEVER (§ 472, *et seq.*). The fact that putrid effluvia generate fever in man has been sufficiently demonstrated to require any illustration at this place, and has been sufficiently proved by evidence referred to in various parts of this work, and by proofs which have come under my own observation. The instances which have been adduced in opposition to it by Dr. BANCROFT, PARENT-DUCHATELET, and others, prove only that these exhalations are not poisonous in every case or occasion of exposure to them, and that habit and other circumstances may impart to some persons an immunity from their usual effects. These exhalations have often produced not only *putrid* or *adynamic fevers*, but also an *adynamic form of dysentery*; and in some cases which I was lately called upon to treat, I had every reason to infer that these exhalations may produce dysentery by their action upon the mucous surface of the anus, when resorting to such privies as contain large accumulations of fecal matters, especially during warm seasons. An asthenic form of irritation and inflammation, with adynamic fever, was observed in these cases, the local affection extending from the margin of the anus upward along the mucous surface of the rectum and colon; and, in three instances, affecting also the vagina and uterus in a similar manner, and with similar discharges.

521. C. When putrid animal matters or fluids are *inoculated* or inserted into *wounds*, or applied to *abraded surfaces*, extensive local inflammation of a diffusive or spreading kind, with very low or adynamic fever, is developed, owing to the rapid contamination produced locally as well as in the circulating fluids, and death takes place, unless the mischief be early arrested by a very active stimulating, antiseptic, and tonic treatment. The injuries received from dissection of putrid bodies, and by cooks when dressing very high game, are of this kind, they being generally attended by a diffusive cellular inflammation and adynamic fever, and are different, in both the local and the constitutional phenomena, from the injuries received in the dissection of recent bodies, although allied to them in many respects. (See CELLULAR TISSUE—Diffusive Inflammation of.) Putrid animal matters occasion somewhat different effects, according to the nature of the matter, the degree of putridity, and the constitution of the individual, but these effects are more or less allied to those produced by poisons which I have viewed as septic, and classed accordingly. (See CLASS SEPTIC POISONS.)

522. D. The Treatment of the effects produ-

ced by putrid animal matters received into the stomach is in every respect the same as that recommended for the poison of pork or of sausages, &c. (§ 443, 450). After the offending matters have been evacuated, either by encouraging vomiting or producing it by the means just advised, *creasote* may be given with the warm spices already mentioned, and these may be mixed with powdered charcoal or in solutions of the chlorides, and taken in doses which the urgency of the case will suggest. If dysenteric symptoms supervene, these medicines may be conjoined with ipecacuanha and opium, or may be administered in enemata; and the rest of the treatment recommended in DYSENTERY, according to the form which the case may assume, may be adopted. I have lately given, in some dysenteric cases which have been produced by putrid animal exhalations, small and repeated doses of creasote, and a weak solution of the chloride of zinc, with marked benefit. The chloride of lime may also be given in small, but often-repeated doses, and lime-water, with milk, or in effervescence, or Carara-water, may be used as beverages. The effects caused by the *inhalation* of putrid effluvia require similar means to those prescribed for the adynamic or putrid forms of fever. (See ARTS. DYSENTERY and FEVER.) The treatment of local contaminations by putrid matter is not different from that about to be recommended for *septic poisons*.

523. xi. TOBACCO.—*Indian Tobacco*—*Lobelia Inflata*.—*Virginian Tobacco*—*Nicotiana Tabacum*.—The poisonous operation of these two plants closely resembles that of each other, the latter being the most energetic.—A. In doses exceeding fifteen or twenty grains, the *Lobelia* causes speedy and severe vomiting, with distressing nausea and sense of sinking at the epigastrium; sometimes purging, cold perspirations, giddiness, headache, tremours, and great relaxation and prostration of strength; failure, with intermissions of the pulse, sometimes a prickly sensation through the body to the extremities, and a smarting in passing the urine. In doses above thirty or forty grains of the powder, it produces death in a few hours, if it be not thrown off the stomach by the speedy vomiting induced by it. The most prominent symptoms are then, according to Dr. WOOD (*Lancet*, April, 1837, p. 144), extreme prostration, great anxiety and distress, and ultimately death, preceded by convulsions. Fatal effects have often resulted from the empirical use of this plant in America, owing chiefly to its not having been rejected by vomiting, as is sometimes the case. The effects produced by it are the same as those now described when it is administered in an enema.\*

\* [The *Lobelia*, or Indian tobacco, is a violent acrid irritant, and has occasioned many deaths from its improper use by empirics. The following cases are examples of the fatal effects of this article when improperly administered:]

The sixth volume of the Massachusetts Reports contains an account of the trial of SAMUEL THOMPSON for the murder of EZRA LOVETT, by administering *lobelia*. It appears that the patient, being confined by a cold, sent for Mr. T., who gave him three powders of *lobelia* in the course of half an hour, each of which vomited him violently, and left him in a great perspiration during the night. The next day two or more powders were given, each of which operated by vomiting, and occasioned great distress. In like manner, two other powders were given the subsequent day, leaving the patient in a state of great prostration. Several days after this, finding the patient still worse, Mr. T. gave sev-

524. *B. Virginian tobacco*, in the present state of society, is one of the most important plants in nature, and one of the most deleterious poisons furnished by the vegetable creation. In whatever way tobacco is used, whether chewed, smoked, or snuffed, habit impairs, and even modifies its effects. Sir B. BRODIE found that the infusion of tobacco thrown into the rectum, paralyzes the heart and causes death in a few minutes; but if the head of the animal be previously removed, and artificial respiration kept up, the heart remains longer unaffected, proving that tobacco disorders this organ through the medium of the nervous system. On herbivorous animals the effects of tobacco are less marked than on man.

525. *a.* In small doses, tobacco causes heat in the throat and warmth in the stomach, followed, especially if the dose be somewhat greater, by nausea, giddiness, and vomiting. In larger doses, it occasions nausea, vomiting, purging, a distressing feeling of sinking at the epigastrium, but rarely any pain. It seldom promotes sleep or evinces any narcotic influence beyond what depends upon its sedative action. In poisonous doses, its most remarkable effects are languor, feebleness, great and depressing anxiety, fainting, relaxations of the muscles, trembling of the limbs; vision and all the senses are enfeebled, the ideas confused. The pulse becomes small, weak, irregular, or intermittent; the respiration laborious; the surface and extremities cold and clammy. Recovery generally takes place if the symptoms proceed no farther; but if the vomiting continue, or if the purging be frequent, the tendency to faint

becomes urgent, the features sunk, the muscular powers paralyzed, the pulse progressively weaker, the extremities and surface colder, and covered by cold sweats; and, ultimately, convulsive movements, general paralysis, torpor, and death take place.

526. *b.* Tobacco is used in various ways, the effects produced by it being remarkably influenced by *habit* in whatever way it may be employed, at least up to a certain amount or dose. In the form of *snuff* it acts locally chiefly. The habitual use of snuff blunts the sense of smell, and, if it be taken in excess, dyspepsia, with peculiar symptoms, and a cachectic appearance of the surface, are produced by it. Dr. PROUT considers the dyspeptic symptoms caused by snuff to be peculiar and severe, and that malignant diseases of the stomach and liver are sometimes occasioned by this practice, when excessive or long continued.

527. *c.* *Smoking tobacco* in any way produces many of the symptoms described above, if it be long continued by a person unaccustomed to it. Dr. M. HALL detailed a case which nearly terminated fatally; the subject of it having, for his first essay, smoked two pipes. Dr. CHRISTISON refers to two cases recorded by GMEIN, which were fatal; seventeen pipes in the one, and eighteen in the other having been smoked at a sitting. This practice has been adopted by some with the idea that it is a prophylactic against endemic, epidemic, and contagious diseases; but there are really no grounds for this opinion. Smoking, especially when very frequently indulged in, weakens the digestive and assimilating functions, lowers the tone of the nervous system, imparts a pale, sallow, and cachectic hue to the countenance and skin, and induces functional disorder of the stomach, liver, and bowels. The soothing and flattering visions with which the practice of smoking feasts the weak and effeminate mind, lead to its adoption by most classes; but it is an enervating and an emasculating luxury; the offspring of those who indulge in it in excess being weak, puny, or stunted in growth; or of a nervous, susceptible, and scrofulous conformation. It often, also, induces a desire for spirituous liquors.

528. *d.* *Chewing tobacco* is even a more deleterious habit than that of snuffing or smoking. It is practiced chiefly by sailors and the natives of the United States of America. In sailors, the sea air probably counteracts its injurious influence; but when commenced in boyhood, as is often observed in this class, it stunts the growth, and in all circumstances it weakens the organic nervous energy and the mental powers, impairing also the powers of application. Persons habituated to this mode of using tobacco are irritable, restless, and miserable when deprived of it, and feel a distressing sinking at the epigastrium. If they continue long to indulge in it, they lose their healthy appearance, and, although they may not evince any severe or specific disease, the nervous system—the mental powers especially, are weakened by the habit, and they become prematurely aged and short-lived. [These remarks can only apply to tobacco when employed in excess; for, as above remarked, “habit impairs, and even modifies its effects.”]

529. *e.* The application of tobacco to a recent

eral more powders, which produced great distress, and at length ceased to operate. Still more lobelia was administered, until the patient lost his reason, and became convulsed so as to require two men to hold him. To relieve these symptoms, two more powders were forced down, and the patient soon expired.

The accused was tried for murder, but for want of sufficient evidence of malice prepense, he was acquitted.

A very similar trial took place before the Court of Sessions in the city of New York, in December, 1837, in which a Thompsonian doctor by the name of FROST was tried for killing a Mr. FRENCH, by the administration of lobelia. In this case, lobelia was freely and repeatedly administered, both by mouth and injection; besides which, the patient was repeatedly steamed, and took large quantities of “composition tea.” This course was continued until inflammation of the stomach, bowels, and brain was induced; delirium, with great prostration, took place, and the patient sank, exhausted.

On this trial, several botanic physicians testified that lobelia was not dangerous in any doses. The accused was found guilty, and sentenced to incur the penalty of fine and imprisonment.

Another trial of a similar kind took place at Binghamton, N. Y., in May, 1844, which is reported in the New York Journal of Medicine and Surgery for November, 1844, by Dr. DAVIS.

The patient had been complaining for some days. The accused, Dr. DRAKE, commenced by giving some medicine to prepare the stomach for an emetic. The next morning he gave at least a tea-spoonful of the seeds of lobelia. About noon, the patient became much distressed for breath: ginger tea was ordered, of which three tea-cups were given; a decoction of lobelia, containing a quantity of the seeds, was next administered in divided doses: convulsions set in, and the patient expired. On a post-mortem examination, a table-spoonful of lobelia seeds was found in the stomach; the mucous membrane of the stomach was softened and much inflamed; the intestines also were much inflamed. The botanic physicians testified that lobelia would not excite inflammation under any circumstances, and that it does not possess poisonous properties. The accused was found guilty. Other cases could be given to the same effect, all going to prove the dangerous effects of this article when given in considerable doses. (See *Bigelow's Med. Bot.*, vol. i., p. 181; *Phil. Journ. of Pharmacy*, vol. v., p. 300; vol. ix., p. 98.)

wound, to an abraded surface, or to sores, is often attended by serious or even fatal effects. Mr. Weston has recorded a case in which the expressed juice of tobacco was applied to the head of a boy, aged eight years, for the cure of tinea capitis. Death took place three hours and a half after the application. Three children were seized with giddiness, vomiting, and fainting from the application of tobacco leaves to the scalp for the cure of an eruption.—(*Ephemer. Cur. Nat.*, Dec. ii., Ann. iv., p. 467.)

530. *f.* Tobacco has not infrequently been employed fatally in an *enema*. I have witnessed this result from half a drachm of the infusion having been thus prescribed. An instance is adduced in the British and Foreign Medical Review (vol. xii., p. 562), in which the decoction of twelve grains in six ounces of water, used as an enema, was fatal. Cases of a similar result from larger quantities of this plant, administered in this way, have been recorded by DESAULT, GRAHL, COOPER, BELL, and others; and it has not infrequently caused death when thus employed by empirics. The symptoms produced by it, thus administered, are similar to those already described; nausea, relaxation of the muscles, failure of the pulse, tremours, faintness, cold sweats, and excessive sinking, or fatal syncope, being the most characteristic phenomena.

531. *g.* The appearances on dissection, as described by Dr. GRAHL, are thus stated by Dr. CHRISTISON. Great lividity of the back, paleness of the lips, flexibility of the joints (two days after death), diffuse redness of the omentum, without gorging of the vessels, similar redness with gorging of vessels on both the outer and the inner coats of the intestines; in some parts of the mucous coat patches of extravasation; and unusual emptiness of the vessels of the abdomen. The stomach was natural, the lungs pale, the heart empty in all its cavities, and the brain was natural.

532. *h.* The operation of Virginian and Indian tobacco is nearly the same. The action of Virginian, or common tobacco, is similar to that of *foz glove*; but it is slightly irritant of the digestive mucous surface, and much more paralyzing, causing more decided relaxation and depression of muscular power, with trembling. It, moreover, acts more decidedly upon the secretions and upon exhaling surfaces. The action of this poison differs from that of *Belladonna*, and from that of *Stramonium* or *Hyoscyamus*, in the contraction of the pupil when applied locally or taken in poisonous doses, and in the absence of any affection of the throat, and of delirium or other cerebral symptoms. The influence of tobacco differs also from that of *aconite*, in its more decided effect upon the muscular system, while *aconite* paralyzes the sentient nerves, occasioning numbness and tingling, which are not observed after the administration of tobacco.

533. *i.* *Treatment*.—Poisoning by swallowing this plant, or preparations of it, is very rare, a few cases only being recorded. The discharge of the poison from the stomach, by the means usually resorted to, should be as speedy as possible. There is no chemical antidote to it yet known; but Dr. PEREIRA thinks that the vegetable acids and astringents, the infusion of nut-galls, of green tea, &c., may be employed

with benefit. In order to allay the vomiting and depression of vascular action, ammonia, brandy, capsicum, and other spices, with small doses of opium; the cold affusion on the head, if congestive or apoplectic symptoms occur; the use of strong coffee; sinapisms over the epigastrium, and the other means advised for the other poisons of this class, are chiefly deserving adoption.

534. xii. VEGETABLE ACRO-SEDATIVES OF DIFFERENT SPECIES, besides those already noticed, have produced serious effects; but their operation, and the symptoms they occasion, have not been satisfactorily observed. The chief of these are the following: *A. CASTOR SEEDS*.—The seeds from which castor oil is extracted contain in the embryo a most active acro-sedative poison, a few of them being sufficient to produce violent purging and death. Mr. TAYLOR adduces the following illustration of their effects: A lady, aged 18, ate about twenty of these seeds, one of her sisters ate four or five, and another two. In the night of the evening on which this took place, they were all taken ill. The deceased, who had taken the largest number, felt faint and sick about five hours afterwards, and vomiting and purging came on, and continued through the night. The following morning she presented all the symptoms of malignant cholera. The skin was cold and dark-coloured; the features contracted, and the breath cold; the pulse was small and wiry; there were restlessness, thirst, pain in the abdomen; and she lay in a drowsy, half-conscious state. Whatever liquid was taken was immediately rejected, and the matters passed by stool consisted chiefly of a serous fluid tinged with blood. She died in five days without having rallied. On inspection, a very large portion of the mucous membrane of the stomach was found abraded and softened in the greater curvature. There was general vascularity of the organ, and the abraded portion presented the appearance of a granulating surface of a pale rose-colour, and was covered by a slimy mucus. The small intestines were inflamed, and their inner surface abraded. The two sisters recovered. Two or three of the seeds act as a violent depressing cathartic. The irritant poison resides in the embryo, and is not expressed with the oil, which, in its fresh, or non-rancid state, is a mild purgative.

535. *B. IATROPHA MANIHOT—Iatropa Manihot*.—The fresh root, or the juice of this plant has been long known as a violent poison. It produces nausea, vomiting, and purging; pain, tenesmus, swelling of the body, loss of sight, coldness of the extremities, faintings, and death. Dr. BECK refers to cases in which the juice had produced these effects within an hour. The dissection of one case furnished no alteration, excepting that the stomach was found shrunk to half its natural size. The noxious property of this plant is destroyed by heat.

536. CLASS VI. IRRITANT AND ALTERANT POISONS.—ACRO-ALTERANT POISONS.—This class of poisons is very closely allied to the *fifth*. It comprises those substances and preparations which, either in acutely or chronically poisonous doses, not only irritate the digestive surfaces, but also alter the vital properties and manifestations of the tissues—not so much dy-

namically, as in the preceding classes, as in character or kind. When administered in large doses, the alterative effects may not become very apparent if they produce death in a short period, if they are so given as to prove *acutely* poisonous; but during their *slower* or more *chronic* operation, and during recovery from their acute action, the alterative effects are more fully evinced. Several of the substances comprised under this class are much employed medicinally, and have been, and even still are, prescribed, although much more rarely, so as to produce most injurious effects, owing to the alterant influence exerted by them upon the functions of several surfaces and organs, and not upon the functions merely, but even upon the organization of the structures ultimately and remotely. There are several substances which have been already considered, that produce also an *acro-alterative* effect, when administered in smaller quantities or in repeated doses. But as these, when employed as poisons or in large quantities, act either as *corrosive* poisons or as *acro-sedative* poisons—in the one case corroding or disorganizing the tissues to which they are applied, and in the other depressing, or altogether annihilating nervous influence or vital power—I have thought it preferable to treat of them under these classes. Even the same poison, however virulent, does not act in a certain definite manner and specific mode, but in different ways, according to the amount, repetition, or continued exhibition of it; and to the various modifying influences already described (§ 51, *et seq.*). Poisons are not to be viewed as specific entities, producing certain and determinate results, but as powerful agents affecting nervous influence, vascular action, vital power and resistance, and even the organization of the frame, in varying modes and grades; the more manifest effects furnishing, by their prominent features especially, such characters as enable us to arrange and classify them. And thus we find that many poisons, as corrosive sublimate, the concentrated acids and alkalies, several mineral and other saline substances, and even the vegetable acids, act as corrosive and acute poisons, and destroy life, chiefly by the intensity of their local action, when taken in sufficient quantity in certain states of the stomach, while the same substances, when administered in smaller or repeated doses, or in states of greater dilution, or when their exhibition has been too long continued, are fatal, or are injurious, owing to different modes of action, and to their remote and secondary effects produced by different channels, their effects having a very intimate reference not only to their quantities and modes of exhibition, but also to the constitution and states of the sufferer at the time. Hence many corrosive poisons, when thus or otherwise exhibited, act as sedatives, or as irritants, or as *acro-sedatives*, and produce effects similar to those classed under these several heads, or act as *acro-alteratives*, and operate in nearly similar modes to those substances now about to be noticed.

537. i. *BELLADONNA*—*Deadly Nightshade*.—*Atropa Belladonna*—*Atropia*—has usually been classed as a narcotic, or *acro-narcotic* poison; but although the last stage of poisoning by it is often attended by sopor or insensibility, it is

not strictly a narcotic, as will appear from the symptoms produced by it. The leaves, roots, and berries of the plant are poisonous, and produce nearly the same effects in equally powerful doses. On dogs, this plant causes dilatation of the pupil, plaintive cries, efforts to vomit, staggering, weakness of the posterior extremities, frequent pulse, a state resembling intoxication, and death (PEREIRA). I have seen dangerous, and in one instance nearly fatal effects result from the medicinal use of preparations of this plant.

538. A. The symptoms vary remarkably with the dose and the frequency of its repetition, with the mode of administering it, and the constitution of the sufferer. The most rapid appearance, and the most comatose state of the symptoms have followed the administration of an infusion or extract of this plant in an enema. Dr. SCHARF states, that four ounces of an infusion of the root injected as a clyster produced coma and death in five hours. In a case to which I was called, the extract had been introduced into the rectum as a suppository, but the exact quantity I could not learn. Apoplectic coma soon followed, from which the patient recovered with difficulty, delirium both preceding and following the coma. The poisonous operation of belladonna is most rapidly and fatally developed, when any of the preparations of it is administered as an enema.

539. a. The local or irritant action of this plant is not very intense, and is exerted primarily upon the upper portion of the digestive canal, especially the fauces and œsophagus, causing dryness and redness of the throat with slight difficulty of swallowing, and but seldom vomitings or purging. In some instances soreness of the throat, difficult deglutition, and even aphthous inflammation of the fauces have been more remarkable; and in rarer cases, bloody stools, strangury, and even bloody urine have appeared consecutively, or have accompanied the nervous symptoms. The irritation of, and eruption on, the skin, characteristic of this poison, appears chiefly after a frequent or prolonged use of small doses of it. This eruption has been observed by me in several instances where I had employed belladonna. It has been likened to that of scarlatina; but it has as frequently resembled the eruption of measles. It has sometimes followed the use of the extract in ointments which I have prescribed for irritable states of the rectum or uterus.

540. b. The alterative operation of the preparations of belladonna is varied and uncertain, and is exerted chiefly on the nervous systems, more particularly upon those portions which are most intimately connected with the manifestations of sensibility and intellect. Thus we observe dilatation of the pupils, insensibility of the irides to light, dimness of vision, diminished feeling, vertigo, staggering, delirium, and occasional sopor, successively follow the excessive use of them. The alterative operation of this poison on others of the systems or organs of the body is problematical, although the uterine functions have been said to have been influenced by it. This plant, especially the tincture and inspissated juice or extract of it, is a valuable remedy, not merely as an anodyne, but also as an alterative in several diseases; but, if exhibited without due caution, especially in

children, or in whooping-cough, it is liable to be followed by injurious or even dangerous effects. Accidents from this poison most frequently are observed in children, who sometimes eat the berries.

541. The husks and seeds of the berries are very indigestible, and may remain long in the stomach or bowels, whether the case recover or prove fatal, especially if free vomiting has not been early procured. In one case the seeds were vomited towards the close of the third day. (*Med. Obs. and Inq.*, vol. vi., p. 224.) In another case the black husks appeared in the stools after the use of laxatives on the second day. In several other cases adduced by M. BOUCHER, fragments of the fruit were vomited on the second day, and passed by stool on the third, although actively treated from the commencement. But this can occur only when the fruit has been taken accidentally or by mistake; but all cases of poisoning by belladonna are not of this kind. Even the administration of preparations of this plant for medicinal purposes may be such as to occasion either dangerous or fatal effects, especially in children; and the juices of it may be given with felonious intentions. They have been so employed, either mixed in wine or in other fluids, in the commission of murder; and even to aid the commission of thefts or robberies; decoctions and infusions of various parts of the plant having likewise been used for the same purposes, as recorded in numerous works of the preceding two centuries. Dr. CHRISTISON remarks, that other species of *atropa* are probably similar in their properties to belladonna. WILMER quotes instances of frantic delirium having occurred among shepherds, as well as their cattle, from eating the *Atropa mandragora*, which was used by the ancients in medicine.

542. *B. Atropia*, the active principle of this plant, is not likely to be employed as a poison. Given to the lower animals, it produced the same symptoms as the berries or the leaves. One tenth of a grain caused in the human subject dryness of the mouth, constriction of the throat, difficulty of swallowing, dilatation of the pupil, headache, and stupor.

543. *C. Diagnosis*.—Whatever part or preparation of this plant may have been taken into the stomach, or otherwise administered, dilatation of the pupil is always observed if the dose is poisonous. This symptom precedes the delirium, the character of which is peculiar and diagnostic, especially when viewed in connexion with the state of the pupil, and the dryness, soreness, or constriction of the throat. The delirium is generally gay, extravagant, pleasing, talkative, more rarely furious. It is sometimes attended by uncontrollable laughter, and occasionally by loss of voice. Vision is obscure, the iris is insensible to light, and the eyeball sometimes red and prominent. A state resembling somnambulism has, in rare cases, been observed. The sopor or lethargy produced in the more severe cases generally does not appear for a considerable time after the poison has been taken. Giddiness first occurs, and is followed by the delirium, which may continue for several hours before sopor takes place; but in some instances the sopor has occurred more early, and has been followed by delirium. Occasionally, even in the same case, the delirium,

which preceded the stupor, returns when the stupor goes off; and very frequently the stupor is not distinct at any stage, showing that this poison should not be classed with narcotics. Convulsions are not frequently produced by it, unless in children; in adults they are slight, or confined to the muscles of the face; but *subul-tus tendinum*, or catching of the extremities, is frequent. The periods at which the symptoms appear vary much. Giddiness may appear in a few minutes, or not until two or three hours, and the affection of the eyes about the same time, or soon afterward. The delirium may be delayed for some hours. These symptoms may continue for two or three days. They generally persist much longer than in cases of narcotic poisoning. In some instances these symptoms, especially the blindness and state of the pupil, giddiness, tremours, and other nervous affections, continue several days, or even weeks.

544. *D. The appearances after death* have not been observed in many instances. In a case described by GMELIN, the subject of it died twelve hours after eating the berries. The body was examined twelve hours after death, and yet putrefaction had commenced, so that the abdomen was swollen, the scrotum and penis distended with fetid serum, the skin covered with dark vesicles, and the brain soft. The blood-vessels of the head were gorged, and the blood everywhere fluid, and flowing profusely from the mouth, nose, and eyes. M. ROQUES describes somewhat similar changes to the above, and states them to be usually found after poisoning by this plant, especially the swelling of the abdomen, livid spots on the surface, exudations of blood, or of a bloody froth from the mucous canals, especially the mouth and nostrils, and sudden and rapid putrefaction, preceded by general intumescence of the body. When the berries, husks, or seeds have not been vomited or passed by stool, they are sometimes found in the alimentary canal, and furnish evidence of the nature of the case; when they have been evacuated, and are detected in the discharges, they assist the diagnosis, which is seldom difficult when any part of this plant has been eaten accidentally, or otherwise administered. (*See* M. ROQUES, *Phytographie Médicale*, t. i., p. 229, *et seq.*)

545. *E. Treatment*.—The speedy and complete evacuation of the poison from the stomach, by means of an emetic of zinc, to which capsicum may be added, in order to arouse the paralyzed organ, should be first attempted, especially when the fruit has been eaten. In these cases the stomach-pump ought not to be confided in alone, although it may be required in aid of the emetic, the free operation of which should be duly promoted. The older writers strongly advised recourse to vinegar, and either it or other vegetable acids will prove serviceable after the poison has been evacuated. The cold affusion on the head and neck is indicated for the removal of the delirium or sopor; but it should not be continued too long at a time. In some cases tepid affusion may be substituted for the cold. Dr. PEREIRA suggests the administration of nut-galls or green tea. I found full doses of camphor and chloric ether successful in a case in which the inspissated juice, administered by the rectum, proved nearly fatal, tepid affusions having been also administered.

546. ii. CANTHARIDES—*Cantharis Vesicatoria*—the Blister Beetle or Spanish Fly—*Cantharidin*—*Vesicatorin*.—Cantharides may be poisonous in any of the forms in which they are employed in medicine—in that of powder, or of tincture, of vinegar, of cerate, ointment, or plaster. Applied *topically*, they excite the nerves of the part, and irritate and inflame the capillaries, occasioning first a sense of heat, followed by pain, redness, and slight swelling. They are readily absorbed into the circulation, or their active principle, *Cantharidin*; and, in addition to their local action, they produce very energetic effects upon the vascular and nervous systems, especially on the spinal cord, and upon the urinogenital organs.—A. Their *local action* is irritant and inflammatory; their *remote operation* is alterative, exciting, irritating, and inflaming, according to the amount and repetitions of the dose; their *primary* influence being exerted on the nervous systems, their *secondary*, or consecutive operation, being produced chiefly through the medium of the blood. They are eliminated by the kidneys, on which, and on the urinary bladder and passages, they produce the effects just described. They are thus closely allied in action to several substances comprised under the class of acrid and corrosive poisons, on the one hand, and to many of those belonging to the excitant and irritating classes on the other. The local action of cantharides is nearly the same wherever they are applied, and their remote effects are also the same, whether they are taken into the stomach or applied to the skin denuded of its cuticle, or to a wound, or thrown into a vein. They have destroyed life when taken as an aphrodisiac, or to produce abortion, or accidentally. They are very rarely employed to produce murder or suicide.

547. B. *Symptoms*.—a. These vary with the mode of exhibiting this poison and the quantity of it administered. When it is taken in large or repeated doses, or to an amount sufficient to produce a *sub-acute form* of poisoning, heat and pain in the throat, stomach, and intestines are experienced. To these are soon added thirst and pain in the loins, extending along the ureters to the bladder, with a burning sensation in this viscus, a frequent desire to evacuate the urine, which is passed frequently, in small quantity, with difficulty, and sometimes more or less tinged with blood. The pulse is frequent and hard, the skin hot, and the respiration quickened. The nervous system is somewhat excited, painful priapism, with or without satyriasis, being also present. In still larger quantity the effects are more *acute*. A violent burning is felt in the throat, gullet, and stomach, with pain and tenderness in the epigastrium, extending over the abdomen, with sickness and vomitings. To these are added extreme thirst, and pain in the loins and bladder; dryness and heat of the mouth, sometimes with fetor or with pyalism; and incessant desire to void urine, the attempts to evacuate it being attended by excruciating pain, and nothing but drops of blood or of bloody urine being passed, and excessive tenderness of the whole abdomen. The heat and constriction of the throat increase, and are attended by distressing difficulty of deglutition. Violent griping pains of the bowels, with purging or with tenesmus, bloody stools, &c., are generally experienced. The difficulty of deglu-

tion is often accompanied with a dread of fluids, although the thirst is urgent, and the matters vomited consist chiefly of mucus, or flakes of lymph streaked with blood. The priapism is painful and constant. The genital organs being swollen and inflamed. In some instances maniacal delirium, tetanic convulsions, and coma supervene, and terminate life; in others the delirium is less marked, giddiness, faintings, sinking of the pulse and vital powers, and other symptoms of gangrene consequent upon acute inflammation, being present. *Death* is more immediately produced either by the inflammation and consequent gangrene of the alimentary canal, or of the genital and urinary organs, or partially of both, or, if the patient live somewhat longer, by the intensity of the nervous symptoms.

548. b. The *duration* of the symptoms depends upon the susceptibility of the individual to the action of cantharides, upon the preparation of it administered, and upon the treatment. The tincture is followed by a more immediate effect than the powder. Even in fatal cases death seldom takes place before three or four days, and it may not occur until after two or three weeks, from the consequence of the inflammation produced in the alimentary canal, or in the urinary passages, or even in the brain, or spinal cord, or their membranes. Sometimes the nervous symptoms do not appear until several days after the ingestion of the poison. The *quantity* which may be considered sufficient to destroy life depends upon the nature and strength of the preparation. ORFILA has seen twenty-four grains of the powder prove fatal; but as abortion was first produced, it is probable that this circumstance not only accelerated, but also aided this result, which occurred on the fourth day. The smallest quantity of the tincture which has caused death is one ounce, the individual having lived fourteen days. But, while smaller quantities may occasion dangerous or even fatal results, much larger may fail of producing very serious effects, the circumstances so frequently referred to remarkably affecting the issue. Instances have occurred of *blistering plaster* having been swallowed by mistake. In one case, half an ounce of the plaster, containing two drachms of the powder, was taken, and death occurred in twenty-four hours (*Edin. Med. and Surg. Journ.*, Oct., 1844), the shortest period in which cantharides have been fatal.

549. c. The application of cantharides to the skin as a *vesicant*, or external irritant, being very generally adopted, is in many cases productive of fatal consequences, owing to the severity of the local alterations, to the intensity of the inflammation and sphacelation they sometimes occasion, and to the spreading of these effects, and, more rarely, to their influence upon the urinary organs and nervous system. The mischief thus produced occurs chiefly in infants or young children of a cachectic habit of body, or in those with either a deficiency or an exuberance of blood, or when the application is too long continued, or is followed by injudicious topical dressings. It is most likely to occur when the blister is applied on children infected with the more adynamic or malignant forms of the exanthemata, especially measles and scarlet fever and is allowed to remain too long upon

the part, or after redness is produced. The admission of the air to the denuded surface, and the application of rancid ointments as dressings, are also often concerned in producing these serious local effects.

550. *C. Apparances on Dissection.*—In the acute cases, and when death has taken place after a few days, the mouth, œsophagus, stomach, and small and large intestines, as well as the kidneys, ureters, bladder, and genital organs, have been found inflamed, and even, in rare instances, sphacelated in parts. In an instance where an ounce of the tincture had been taken, and death did not occur until the fourteenth day, the villous coat of the stomach was not inflamed, but it was pulpy and easily detached; but the kidneys were inflamed. In the most rapidly fatal cases the powder may be detected adhering to the villous coat of the stomach. In more prolonged cases, congestion or increased vascularity of the brain, cerebellum, spinal cord, and their membranes have been observed. Ulceration of the bladder in some instances, and even sphacelation of the genitals, have been mentioned.

551. *D. Treatment.*—Cantharides are productive of severe irritation passing into acute or sub-acute inflammation, according to the quantity administered; and their absorption is followed by inflammation of the urinary organs, and by excitement, and sometimes by inflammatory irritation of the nervous centres. The indications of treatment are hence obviously, 1st. To remove the poison by emetics, and by encouraging vomiting; and, 2d. To allay the inflammatory action in these parts. When the sufferer is seen sufficiently early, and vomiting has not commenced, ipecacuanha should be given in copious emollient and demulcent draughts, and its operation promoted by tickling the fauces, by the tepid infusion of chamomile, &c. The inflammatory symptoms require general and local blood-letting; but if there be reason to infer that any of the poison still remains on the stomach, the discharge of it should be procured or attempted previously to resorting to depletions, lest absorption be promoted. When blood-letting is prescribed, it should be employed in a decided manner, and aided by demulcents containing small or moderate doses of camphor and nitre, with opium, henbane, &c. Emollient injections into the large bowels and into the bladder, and warm baths, hip-baths, fomentations, &c., are always beneficial. Oil was once supposed to be an antidote to cantharides; but there is no known antidote to this poison; and oil is now ascertained rather to aggravate than to alleviate the symptoms, by dissolving the active principle of cantharides.

552. Poisoning by the external application of cantharides requires the same treatment as now advised. In these cases, the urinary organs are generally more affected than the digestive canal, and diluents, demulcents, opium with camphor, are chiefly required, unless in the more severe cases, when blood-letting is necessary. But these cases generally soon recover, unless the poison be applied to a very large surface or to a recent wound; and in these the protection of the surface from the air and full doses of opium are requisite. During recovery the digestive and urinary organs long remain irritable, and the nervous system sus-

ceptible; therefore a bland farinaceous or vegetable diet should be adopted, and continued for some considerable time, and flannel worn nearest the skin.

553. iii. CHLORINE AND THE CHLORIDES.—*A. Chlorine gas* produces violent spasm of the glottis if it be inspired in a pure state.—*a.* Mixed with air it causes a sense of tightness of the chest, of suffocation and violent cough, owing to the irritation of the bronchi and spasm produced by it—a state of artificial asthma. [Chlorine is apt to produce severe pain in the back part of the head, and a powerfully depressing effect upon the circulatory system, as we have repeatedly witnessed.] This effect, if not excessive, generally passes off with increased mucous expectoration. When much more diluted with air, it occasions a sensation of warmth in the chest, and promotes expectoration. As a principal fumigating and disinfecting agent, it is liable to produce injurious effects, when air too strongly impregnated with it is breathed; but it is chiefly in manufactories that it is most likely to be hurtful, although the irritating effects of chlorine are less powerful on those accustomed to inhale it. Dr. CHRISTISON was told by a chemical manufacturer in Belfast, that his workmen can work with impunity in an atmosphere of chlorine, where he himself cannot remain above a few minutes. The chief effects produced by inhaling this gas by the workmen are more or less emaciation from the absorption of fat, acidity and disorder of stomach, which are usually corrected by chalk.

554. *b.* When diluted with air, or aqueous vapour of 116° F., and applied to the external surface, it produces peculiar sensations similar to the stinging of insects, accompanied with copious perspiration and determination of blood to the skin, and sometimes followed by an eruption of minute papulæ. In a pure form, its action on the skin is similar, but more energetic. A repeated or prolonged application of the gas to the skin is followed by soreness of the gums and mouth, or fauces, occasionally by slight ulceration, and generally by a more abundant as well as altered state of the salivary and biliary secretions. Mr. WALLACE believed that it tranquillizes while it excites nervous power; and Professor ALBERS, that it is stimulating locally, and antiphlogistic remotely. Many years ago, I examined its operation with Mr. WALLACE in London (in 1823), and subsequently in Dublin (in 1834), and inferred that it is locally irritant or stimulating, according to the amount of dilution, and remotely alterative as regarded nervous power and glandular action. Whether inhaled or applied to the external surface, it is absorbed, as shown and ascertained by Mr. WALLACE and myself, by the state of the urine.

555. *c. Treatment.*—It is chiefly owing to its accidental inhalation in too strong a state of dilution that injurious effects have arisen from this gas. The inhalation of the vapour of warm water, of the spirit of wine, or of ether, has been recommended for the removal of the effects of chlorine; but Dr. PEREIRA states, that he has tried these when suffering himself, without the least benefit. In a case related by KASTNER, sulphureted hydrogen was said to have afforded great relief; but this agent should be used with great caution, as it is itself a powerful poison.

556. *B. Chlorate of Potash* was supposed to be an active stimulant and antiseptic, and, in large doses, an irritant poison. I have frequently employed it since 1816, both in public and private practice, especially in the more malignant states of disease, as an antiseptic, disinfectant, and tonic; but I have been much disappointed in its effects, which I have not found such as I expected, or by any means certain. It, however, diminishes the fætor of the excretions, even those from the skin, as evinced in the putrid and adynamic states of fever, and it is absorbed into the circulation, from which it is excreted chiefly by the kidneys; and it may be detected unchanged in the urine. I have employed it in large doses without obtaining other effects than nausea and vomiting. It appears to be locally irritant, and remotely alterative and diuretic.

557. *C. The chlorides and the hypochlorides of soda and lime* produce effects much resembling those caused by chlorine; but these vary remarkably with the degrees of dilution. In concentrated states they are caustic and irritant; in states of dilution, irritant or stimulant, antiseptic and alterative. I employed these substances largely in practice, especially public practice, when they were first discovered, and found them useful in dysentery and malignant forms of disease; the secretions and excretions in which they remarkably corrected and improved, while they appeared, particularly when aided by appropriate medicines, to support the powers of life. I am, however, unacquainted with injury from the administration of them. When taken in excessive doses they are most likely to occasion gastro-enteric irritation, for which albuminous fluids, the whites of eggs, milk, and oleaginous or mucilaginous diluents are the most suitable remedies. If these salts have been taken in very large quantity, emetics or the stomach-pump may be required; and, after they have been evacuated by these means, these fluids should be abundantly exhibited. Acids must be avoided, lest they should disengage chlorinic gas in the stomach (PEREIRA).

558. *IV. IODINE, THE COMPOUNDS OF.*—The corrosive action of pure iodine, and of strong solutions, or rather tinctures of it, has been already considered (§ 179, *et seq.*). It remains only to notice the locally irritant and remotely alterative injurious effects of the compounds of this substance, or of small doses of it, when either too long employed, or given in such forms as produce *slow or chronic poisoning*. The preparations most likely to produce these effects are the *tinctures* and the *iodides*, as the iodide of potassium, or the iodurcted iodide, the iodide of sulphur, and the iodide of iron. In some constitutions, any of the preparations of iodine occasion, even before a few doses of either are taken, and although the doses are very small, remarkably depressing effects, and generally without any signs of local irritation. I have met with several instances of this very unusual and severe effect of these preparations in practice, and in three of these, the preparations of colchicum were also injurious in very small doses. In general, iodine is not hurtful unless the dose is considerable, or be repeated too frequently, or its use too long continued.—*a. The irritating operation of iodine is most read-*

ily manifested by irritable temperaments and dyspeptic persons. In these, and in other persons in larger doses, it occasions nausea, loss of appetite, cardialgia or heat of stomach, subsequently colicky pains, relaxation of the bowels, diarrhœa, salivation, diuresis, &c. If this substance, or any of its compounds, be still administered, these effects go on increasing, and are attended by soreness of the mouth, severe colic with diarrhœa, emaciation, rapid absorption of the fat surrounding the inammary glands in females; headache, vertigo, sometimes drowsiness or stupor. When iodine is taken in smaller doses, so as not to cause injurious irritation, it acts as a tonic and alterative, and improves both the strength and flesh. But, if too long persisted in, several of the above effects afterward appear.

559. *b. In larger or more frequently repeated doses*, the effects are more severe, and amount to what have been designated *iodism*. These are generally severe vomiting and purging, colicky pains, thirst, and fever; a frequent, small pulse, sometimes a dry cough; cramps of the extremities; rapid emaciation, with occasionally a darker hue of the skin and hair, especially if the iodine has been taken for a long period. In some instances wasting of the *manimæ* or testes, and most of the symptoms of chronic gastro-enteritis. It is rare, however, to meet with instances of these effects from iodine, unless it have been given in a most imprudent manner, or too long persisted in, and even then something should be imputed to idiosyncrasy.

560. *c. In still larger doses* the symptoms either approach, or are identical with, those attending the corrosive form of poisoning by iodine (§ 182). When iodinic preparations have either been long continued, or often repeated, especially in large doses, so as to produce not merely an irritant operation, but also a constitutional change—a marked alterative effect, various contingent phenomena, of a more or less severe character, referable either to the nervous system or to the heart and lungs, are apt to appear, especially stupor, tremours, vertigo, faintness, irregularity of the pulse, alarming sinking, shortness of breathing, restlessness, and even death. In these cases the system may be viewed as saturated with the iodine, notwithstanding that the kidneys have been eliminating it from the circulation, as proved by its presence in considerable quantity in the urine; for it has been detected in the viscera and tissues in such circumstances, and even several days after the administration of iodine had been relinquished. The *appearances in fatal cases* have been already described (§ 183).

561. *d. The treatment of the more chronic or acro-alterative form of poisoning* by any of the preparations of iodine, consists in the removal of gastro-enteric irritation by local depletions and counter-irritation. Demulcent and mucilaginous substances should be given with the preparations of opium or of poppy; and starch or emollient enemata, with sirup of poppies or the tinctura opii composita, should be thrown up from time to time. Warm baths are generally useful. The diet should be chiefly farinaceous or amylaceous, with or without milk; and during convalescence, the regimen and diet recommended for *gastro-enteritis* and the more inflammatory states of *indigestion* ought to be adopted.

562. *V. MERCURY, THE PREPARATIONS OF.*—The poisonous operation of the *bi-chloride* has been already considered (§ 215). But life may be destroyed or put in jeopardy by an excessive or prolonged recourse to any of the preparations of this metal.—*A. Fluid mercury* is inert when swallowed as long as it retains its pure metallic state; but it may be slightly oxydized in the alimentary canal, and thus acquire activity, especially if it be long retained in the bowels. Many years ago it was the fashion to swallow fluid mercury, and, more recently, large quantities of it were often given in order to remove obstructions. It rarely, however, produced unpleasant effects from having become oxydized. ZWINGER states, that four ounces occasioned profuse salivation four days after swallowing it; and LABORDE records the case of a man who retained seven ounces for fourteen days, and was attacked with profuse salivation, ulceration of the mouth, and paralysis of the extremities. I was lately called to a man who had taken, some time previously, seven pounds' weight of fluid mercury with a suicidal intention. His medical attendant informed me that it produced a painful sense of weight and constriction in the abdomen, the body having been bent forward; but it caused no farther disorder, and continued to pass off at intervals for some days.

563. It was not unusual, during the last and preceding centuries, to wear belts with fluid mercury around the body for months, or even years; but the practice was not always devoid of harm; for, in some cases, profuse salivation, and other specific effects of this metal, appeared either suddenly or with great severity.

564. *B. The injurious effects of mercurial vapours* have been shown in the article on ARTS and EMPLOYMENTS, as causing Disease (§ 24, *ct seq.*); and the *trcnor mercurialis*, with the several cachectic and cerebral symptoms associated with it, is there described. This form of *shaking palsy—tremblement mercuriel*—is chiefly met with in workmen whose employments subject them to mercurial vapours. If the emanations still continue to operate, in any circumstance of their evolution, various cachectic symptoms, vertigo, loss of memory, imperfect and unsteady action of the muscles, slight atonic convulsions, and even delirium, epilepsy or apoplexy, terminating in death, are the not infrequent results. Salivation, ulceration of the mouth and gums, hæmorrhages, and emaciation are frequently also produced by mercurial vapours. In 1810, the Triumph man-of-war, and a small vessel, received on board several tons of quicksilver at Cadiz. Owing to the rotting of the bags the mercury escaped, and the whole of the crews became more or less affected. In the course of three weeks 200 men were salivated, and two died. All the lower animals in the vessels—cats, dogs, sheep, fowls, rats, mice, and cockroaches—were destroyed.

565. *C. The mercurial compounds* are all injurious, not excepting even the sulphurets, when taken in excessive quantities, or when their use, even in small doses, is very long continued.—*a. The local action* of mercurials is irritant and alterant; but the bi-chloride and nitrates, in states of more or less concentration, pass beyond this state of action, and are, as shown above (§ 215, *et seq.*), caustic and corrosive, al-

though, when very much diluted, they, as well as the chlorides, diminish both irritation and vascularity in the surfaces to which they are applied.

566. *b. The consecutive and remote operation* of mercurials vary with the preparation and the modes of employing it. When taken internally in *small doses*, they promote all the abdominal secretions and excretions, especially the biliary and pancreatic secretions. If the doses be *repeated*, these effects are not only increased, but others are also added; the mucous surfaces and skin manifest an augmented exhalation, the gums become red and tender, the urinary secretion is increased, and the catamenia promoted; absorption proceeds more rapidly, the pulse becomes somewhat accelerated, and the strength slightly impaired. The repetition or number of the doses, as well as the amount of each required to produce these changes, vary with the constitution and idiosyncrasy of the individual, and the amount of action upon the bowels. If the mercurial be continued longer, or after these effects commence, or if the doses be larger than are necessary to produce them, the redness and tenderness of the gums pass into swelling; the tongue, which was at first broad and soft at its edges, becomes flabby and swollen; a coppery taste is perceived in the mouth, which, with the gums, is sore and tender; *salivation*, more or less profuse, supervenes; the salivary glands are tender and swollen, the teeth are loosened, the breath betrays a peculiar odour and fetidity; the pulse is now more accelerated, the strength much impaired, and emaciation more rapid as the salivation proceeds and increases; the quantity of saliva discharged sometimes amounting to several pints in the twenty-four hours. Such may be said to be the *first stage* of chronic poisoning by mercurials, as frequently produced formerly for the purpose of curing certain diseases, especially the venereal disease; but now very rarely required either for this or any other distemper. During salivation, the urine, according to Dr. PEREIRA, does not contain a trace of albumen. The mercurial action alters the secretion of the salivary glands, and causes it to approach more nearly the fluids exhaled from inflamed serous membranes.

567. *D. The first stage* of poisoning by mercurials is generally such as now described; but occasionally other and more serious phenomena appear after a more or less liberal recourse to any of them, and *assume the features of distinct maladies*. An acquaintance with these contingent effects of the constitutional action of mercurials is of great importance to the practitioner. They are not so much owing, in most instances, to the preparation employed as to the idiosyncrasy, or the state of health of the individual; a scrofulous constitution, the venereal taint, and other causes favouring their occurrence. The maladies which may be ranked under the first stage of chronic poisoning by mercury are, *first*, what has been called *mercurial disease—Morbus mercurialis, hydrargyrosis, cachexia mercurialis, &c.*, and which presents various forms or states; and, *second*, what has been named *pseudo-syphilis*, or *cachexia syphiloidea*, or what is supposed to be syphilis modified by the mercurial disease.

568. *1st. Mercurial disease* may be viewed as

the generic appellation of several morbid conditions resulting from mercurial preparations—from a few grains only of blue pill or of calomel in some constitutions, or from large and repeated doses of these or of other compounds of the metal in others.—(a) *Excessive salivation*—*Ptyalismus mercurialis*—*Stomatitis mercurialis*—may occur from a small dose of any mercurial, or from large or excessive doses. It is oftenest met with after small or moderate doses, and is then the result of peculiarity of constitution. The mouth rapidly becomes violently affected; the tongue is swollen so that it hangs out of the mouth, and prevents the patient from speaking and eating; the gums are tumefied and ulcerated, ulceration often extending to the cheeks; the teeth are loosened or drop out, owing to the sloughing of the gums; the salivary glands are enlarged, tender, painful, and the surrounding cellular tissue congested or infiltrated; and the quantity of salivary discharge remarkably increased, sometimes ten or twelve pounds being secreted in the twenty-four hours. With the progress of these symptoms debility and emaciation make rapid progress; and, with sloughing of the gums, caries of the alveolar process not infrequently takes place. If the mercury be continued, involuntary movements of the muscles, or states of incomplete palsy may appear, and the patient sink from extreme vital depression. Even when the mercury is relinquished, the inordinate salivation and other symptoms may still continue, and be arrested with the greatest difficulty. Indeed, such is the case whenever this effect follows the use of a small dose of mercury, and depends upon idiosyncrasy. In some instances, the ulceration and sloughing are followed by contraction of the arches of the palate, and by inability to open the mouth sufficiently. Occasionally the salivary glands become remarkably enlarged, tender, and inflamed, and the surrounding parts swollen (*Parotitis mercurialis*), and the mouth ulcerated, before the salivation commences, the salivary discharge relieving the extreme swelling and pain of the glands; but this most frequently occurs when the patient has been exposed to currents of cold air, or to cold and humidity upon the accession of the mercurial action.

569. (b) *Mercurial Purging*.—*Diarrhœa mercurialis*.—Excessive purging occurs sometimes after a moderate dose of a mercurial; and may arise from an excessive accumulation of bile in the gall-bladder and ducts having been suddenly let loose, in which case the evacuations are greenish or dark; or from an excessive secretion of the pancreatic fluid having been produced, and then the evacuations are pale, watery, frothy, or ropy, and are attended by pain, heat, or tenderness in the region of the pancreas. (See *PANCREAS, Diseases of*.) Excessive diarrhœa after mercury has been ascribed by DIETERICH (*Die Merkurialkrankheit*, Leips., 1837) to a species of pancreatic salivation caused by mercury, and called by him *ptyalismus pancreaticus mercurialis*, or *ptyalismus abdominalis, diarrhœa salivæ*, &c.

570. (c) *Mercurial fever*.—*Febri mercurialis*.—*F. salivosa*—is generally caused by the excessive use, or by very large doses of mercury, and seldom appears until after some days. It is attended by dryness of the mouth, redness

and swelling of the gums and tongue, great acceleration of pulse, with restlessness, headache, hot and dry skin; swelling or tenderness of the parotids, sometimes extreme, as already noticed (*Parotitis mercurialis*), and loss of appetite and nausea. This state of irritative fever generally terminates with a profuse salivation, more rarely with purging or sweating, or with some form of cutaneous eruption (§ 574).

571. (d) *Mercurial cachexy*.—*Cachexia mercurialis*.—is a more frequent consequence of the prolonged use of mercury, and even of the repeated exhibition of calomel, than is generally supposed; and, as far as my own observation extends, it constitutes, in various modifications, the most frequent form of slow poisoning by mercury. It is not infrequently produced by prolonged efforts to affect the salivary glands in the treatment of hepatic or other diseases, and is characterized by the usual symptoms of irritative fever, without flushings, but with great pallor, emaciation, and manifest æmîa. There are, also, loss of appetite, depression of spirits, disordered bowels, with offensive stools; and occasionally swelling of the salivary glands, redness or sponginess of the gums, or ulcerations of them and of the mouth, cheeks, &c., but rarely any salivation. It usually passes almost insensibly into tubercular phthisis.

572. (e) *Mercurial Erethism*.—*Erethismus mercurialis*.—This alarming affection, thus denominated by Mr. PEARSON, has been viewed by DIETERICH as adynamic mercurial fever—*Febri mercurialis adynamica*. Since Dr. DIETERICH wrote, one case of it has come under my observation; and my examination of that case, as well as my recollection of former cases, has not furnished evidence of the accuracy of this view. The symptoms of this affection are, rapid depression of strength, with a sense of sinking and anxiety, referred chiefly to the præcordia; with partial or general tremour, frequent sighing, universal sense of coldness, and diminished temperature of the surface. The pulse is small, quick, and weak; the countenance is pale, collapsed, and expressive of anxiety and alarm. Vomiting sometimes supervenes, and favours reaction and recovery. In the case just alluded to I could detect nothing, by the aid of the stethoscope, beyond absence of the impulse of the heart, and very weak, frequent, and occasionally irregular contraction. A fatal termination has followed muscular exertion. This affection appears to consist of extreme depression of vital power, and of muscular irritability, manifested chiefly by the heart, and of congestion of the lungs; and hence it might be more appropriately called *Asphyxia cardiaca mercurialis*.

573. (f) *Neuroses Mercuriales*.—Various nervous and mental disorders are sometimes produced by mercury, especially when any of its preparations have been long persisted in, owing to the depressing and alterative action on the nervous systems, probably aided also by other influences. *Melancholia*, sometimes attended by delusions, and various states of partial insanity, in which fears of impending or future calamities more or less predominate, and even sway not only the feelings and sentiments, but also the volitions and actions, are not infrequently produced by a frequent recourse to mercurial preparations. Tremours or trem-

blings (*tremor mercurialis*), sometimes passing into palsy (*paralysis mercurialis*), hyponchondriasis, &c., are also not infrequently occasioned by this cause, and are duly considered at other places.

574. (g) *Various affections of the external surface and of other parts of the body are sometimes produced by an excessive use of mercury; yet it is extremely probable that they are not owing to this cause alone, but to peculiarity of constitution, or to some pre-existing taint or local vice. Certain acute and chronic eruptions on the skin sometimes appear as the effects of inercury; but are now more rarely met with since severe courses of this mineral have been much less frequently resorted to. Eczema mercuriale, Erythema mercuriale, Lepra mercurialis, Erysipelas mercurialis, Hydrargyria, are the names which have been given to an acute eruption which has sometimes appeared during a severe mercurial course, and been attended by considerable danger. This affection has been described by PEARSON, ALLEY, MORIARTY, STOKES, SPENS, CULLERIER, LAGNEAU, RAYER, and others. It generally consists of innumerable minute pellucid vesicles, which give a diffused red appearance to the skin, and a sensation of roughness to the touch: it is generally preceded and attended by more or less febrile disturbance. In two or three days the vesicles attain the size of pin's heads, and the contained serum becomes opaque and milky. The eruption soon extends over the body, and is accompanied by swelling, tenderness, and itching. It usually terminates by desquamation; but a copious discharge sometimes takes place from the excoriated surface; and, with the epidermis, forms large flakes. In some instances the hair and nails fall off, and the eyebrows become denuded (PEREIRA). There is also more or less internal disorder, especially tightness and oppression in the chest, dry cough, with indications of congestion of the lungs and bronchial irritation. ALLEY saw forty-three cases of this eruption in the first ten years of this century, and of this number eight were fatal; more recently RAYER met with only three cases; and PEREIRA only with two. I have seen only two cases, and these occurred at an early period of my practice. Other cutaneous eruptions have been said to be sometimes caused by mercury, especially a miliary eruption, Herpes, Impetigo, Psudracia, &c.; but this origin is doubtful, and most probably other causes concur, if not entirely produce them.*

575. h. Congestions and inflammations of various parts, especially of the eyes, or certain tissues of the eye, as the iris, the retina, the conjunctiva, &c.; congestions and inflammations of the periosteum (*mercurial periostitis*), and caries of the bones, especially of the more spongy bones; and similar diseases of the pericranium, bones of the cranium and dura mater, have also been ascribed to mercury, but are often owing more to a venereal taint, to the scrofulous diathesis, or to idiosyncrasy, than to this mineral; although exposure to cold, and vicissitudes of temperature and weather in a cold or variable climate sometimes produce those diseases which assume a peculiar character during the mercurial saturation and action, especially when aided by the constitutional taints just alluded to.

576. 2d. In this way, also, may be explained the several morbid conditions which are comprised under the denomination of *Cachexia syphiloidea—Pseudo-syphilis*. The modes, also, of employing mercury in the cure of venereal or other maladies, and the various grades or states of saturation of the system which these modes induce, may have some influence in producing various affections of a peculiar or anomalous character; for it may be anticipated that the large doses of calomel, given in a warm climate, will affect the constitution much less, and somewhat differently from the large unctions of mercurial ointments, sometimes more or less altered by long keeping, so often employed in this and other cold climates, especially in former times; and that even the blue pill may be so changed by keeping, particularly in hot and humid countries, as to act differently from the recent preparation.

577. E. *Acute poisoning* by excessive or large doses of mercurial compounds—by single or repeated doses—is generally attended by symptoms of acute gastro-enteritis; but these, as well as the more remote effects, vary with the preparation administered. In general they are altogether the same as are described when treating of the *corrosive operation of the salts of mercury* (§ 216–228), or differ merely in severity, and as respects the liability to any of the consecutive effects just described.

578. F. *Intolerance of Mercury.*—The injurious effects now described are usually produced by a prolonged or an excessive use of any of the preparations of mercury, excepting probably the sulphurets; but in some constitutions very small doses may occasion excessive salivation and some of the other slighter effects, and even a single small dose may have the same result. When salivation follows a single dose it usually appears on the second or third day, and rarely sooner, but occasionally later. It may, however, appear much sooner, and with great severity, considering the dose, when the preparation, as calomel, is allowed to remain in the mouth for some time. In an instance mentioned by Dr. BRIGHT, five grains of calomel put on the tongue in apoplexy, and not washed down, excited in three hours most violent salivation. Dr. RAMSBOTHAM states, that fifteen grains of blue pill, taken in three doses, one each night, produced fatal salivation (*Med. Gaz.*, i., 75). Dr. CRAMPTON records a case where two grains of calomel caused pyalism, extensive ulceration of the throat, exfoliation of the lower jaw, and death. (*Trans. of Dub. Col. of Phys.*, iv., 91.) Dr. CHRISTISON says that three drachms of mercurial ointment, applied externally, caused violent pyalism and death in eight days. (*Op. cit.*, p. 379.) I have seen one grain of the bi-chloride divided into twenty doses, of which one was to be taken thrice daily, produce very severe pyalism before more than two thirds of the grain was taken. I have also seen one grain of blue pill cause very serious pyalism; and the same quantity of hydrargyrum cum creta occasion most severe diarrhoea, the smallest doses of any mercurial having this effect with that individual. During the present epidemic influenza (1847), nine grains of blue pill, in three doses, caused sloughing, ulceration of the mouth, and extreme prostration in a case to which I was called.

579. *G.* On the other hand, some constitutions resist the specific effects of mercury most obstinately. But it must not be supposed that, although the specific effects do not appear, the mercurial has no effect. It may produce some one or more of the injurious effects above described, or it may affect the bowels, and be carried off by diarrhoea, or excite organic disease of the colon or rectum, especially the latter, or occasion mental disorder with irritative fever. It has also been erroneously supposed that calomel and other preparations of mercury are not injurious to infants and young children. Because the specific operation very rarely appears in them. But this is not altogether the case, for the constitutional powers and the digestive organs often suffer more or less, although not manifestly, or at the time; and in older children several of the injurious effects which I have mentioned not infrequently occur, especially ulceration, or even sloughing of the cheeks and gums, and irritative or hectic fever, with remarkable pallor, anæmia, or chronic irritation of the bowels, with enlargement of the mesenteric glands.

580. *H.* The diagnosis of mercurial salivation is always difficult, unless the exhibition of some mercurial shortly before the appearance of the discharge be admitted or ascertained. And even when the admission is made, the quantity may be so small as to allow of doubts as to its influence. In certain constitutions, and especially in depressed and debilitated states of such constitutions, after exhausting discharges, and during cold, humid, and northerly winds, with more or less exposure to such weather, a small dose of a mercurial may cause excessive salivation; and, if this discharge be attended by much soreness of throat, it is most difficult to determine whether the salivation is actually the result of the mercurial, or merely symptomatic of the sore throat and cold. If it proceed from the mercurial, there will generally be some tenderness of the gums, a soft and flabby state of the sides of the tongue, and it will generally be more obstinate. A patient under my care took, under the circumstances of general health and exposure just mentioned, five grains of blue pill. In two or three days afterward he was attacked with salivation and sore throat. He possessed, however, no constitutional tendency to be affected by mercury; and yet this dose, in his existing state, and from exposure to cold and humidity, appeared to have occasioned the attack, which probably, also, the sore throat aided to develop. When severe and prolonged salivation has been once produced by a course of mercury, a very slight cause may reproduce it a long period after it has ceased. A common sore throat or cold is sometimes alone sufficient to have this effect. But in this case, as well as in others not caused by mercury, there is no mercurial fœtor; for, although the breath is often very offensive in non-mercurial salivation, the peculiar mercurial fœtor is absent. A very severe or even dangerous effect may be produced on the mouth by a very small dose of mercurial, when conjoined with or given at the same time as tartarized antimony or colicium.

581. *a.* It ought also to be recollected that several medicines and poisons occasionally excite salivation. The preparations of gold pro-

duce this effect as certainly as those of mercury. Those of copper have often a similar operation; and those of iodine and antimony occasionally exert it. Digitalis and prussic acid sometimes occasion the same effect, and even croton oil and opium have increased this secretion; but this operation, as respects these last, has been loosely observed and recorded.

582. *b* An idiopathic or spontaneous form of profuse salivation has sometimes been met with, no medicinal or poisonous cause of it having been detected. Several cases of this form have been recorded, and have continued for months, or even for two or three years, many ounces of saliva having been discharged daily; but in many of these cases the mouth was not affected, and other characteristics of mercurial salivation were wanting. The imagination may excite salivation. Dr. CHRISTISON met with an example of this, which, with other cases of spontaneous chronic salivation, he has noticed in his work. I have seen an instance of profuse salivation follow the contemplation of a disgusting object, but it did not continue longer than a few days. Some of the cases recorded as instances of idiopathic salivation have probably been symptomatic of chronic or structural disease of the pancreas, as noticed in the article upon that organ.

583. *c.* Dr. CHRISTISON very correctly remarks, that, in general, mercurial salivation may be distinguished from all other varieties, if its progress has been traced from the first appearance of brassy taste and fœtor to the formation of ulcers and supervention of pytalism. Its characters are also quite distinct at the time salivation just begins. The factor of the breath and sponginess and ulceration of the gums at this stage distinguish it from every other affection. But if the mouth is not examined until the ulcers have existed several days, the characters of the mercurial action are much more equivocal. They may not, for example, be distinguished from spontaneous ulceration of the mouth, depending upon general cachexia or unsoundness of constitution, and characterized by extensive ulceration, or sloughing, with pytalism and gangrenous fœtor. The diagnosis of mercurial salivation demands in all cases much attention, not only in a medical or practical, but also in a medico-legal point of view; and, in both regards, there are other questions connected with it which require a special attention.

584. *1st.* May salivation not appear until a long period has elapsed after the administration of the mercury has been abandoned? Mercury administered in small doses is a cumulative poison, and often produces no effect upon the salivary glands or gums until a certain amount of saturation is produced, this amount varying with different constitutions, or with the same constitution at different times. Hence it may be inferred that mercury may accumulate in the system without producing its specific effects, and may still remain, in some instances, for a considerable period, being unexcreted, or only partially excreted, but, before its elimination is accomplished, a change in the state of vital power, or of the constitution, takes place, or some new influence comes into operation and develops the specific action of the mercury existing in the frame. Thus may be explained

the occurrences of salivation not until some months after mercury has been relinquished. SWEDIAUR has met with instances where the interval was several months; CULLERIER with an instance where it was three months.

535. 2d. *What is the duration of mercurial ptyalism, or how long may salivation continue after the use of mercury has been abandoned?* Rare instances of very prolonged salivation have been met with by most practitioners—instances of even several months' duration. But cases have been recorded by LINNÆUS, SWEDIAUR, COLSON, and others of its continuance for periods varying from one to five or six years. These, however, are very rare. Most commonly the mouth and salivary glands return to their healthy states in the course of a fortnight or three weeks; but it is not unusual to observe the period protracted to a month, or even longer.

536. 3d. *May ptyalism, and other specific effects of mercury, recur after a complete intermission, or, in other words, reappear after having entirely ceased, mercury having been discontinued?* I have above (§ 530) admitted this occurrence. It has not infrequently been observed by those practitioners who in former days were very conversant with the effects of severe or prolonged courses of mercury. Dr. CHRISTISON believes that the occurrence of salivation after two, or three, or four months have elapsed, without the repetition of mercury, is exceedingly uncommon. It certainly is so at the present day; but it most probably was not so many years ago, when prolonged and severe courses of mercury were often prescribed; and that it was not so formerly, the reasons assigned above (§ 534), as well as the testimony of HAMILTON, MEAD, MALE, FORDYCE, COLSON, and others, sufficiently show.

537. 4th. *In what manner does small or other doses of mercury prove fatal?* Death may ensue from the mildest preparations, and even from comparatively small doses, generally in consequence of severe salivation, or of gangrenous destruction of parts of the mouth and fauces, and the vital depression produced by the mineral and by the local disorganization. The most obvious manner in which death takes place is by extension of sloughing, or gangrene, of the throat, mouth, cheeks, face, and neck. This result is seldom seen at the present day; but cases are met with in consequence of peculiarity of constitution, or of large doses given to children under the belief that they are much less susceptible of the specific effects of this mineral than adults. In general, when gangrene is the cause of death, it begins within the mouth or in the throat, and spreads from thence until it reaches the face. This is most frequently seen in children. But I have seen the ulceration both commence in and extend to the pharynx, and thence to the larynx, producing destruction of this latter part, and death. Sometimes, especially in children, the sloughing begins on the external surface, at a distance from ulceration of the gums and mouth, appearing in the course of a few days after salivation. A small vesicle generally appears on the skin, on one or both sides near the mouth, and is succeeded by a gangrenous or sloughing ulcer, which spreads over the cheek, and proves fatal in a few days. In cases of this nature, both

the local disorganization and dissolution are the results of the depression of vital power produced by the mineral. When salivation is excessive or prolonged, death may ensue from the exhaustion thereby produced. But even in this case the mercury has occasioned a poisonous vital depression, the first manifestations of which have been the salivation caused by it; but with this depression, and the exhaustion consequent upon the discharge, the changes produced by mercury in the constitution, and the physical appearances and the alterations of the blood, should be taken into the account. Mercury may also excite pulmonary and laryngeal phthisis, and cause death, as just mentioned, by the ulceration of the epiglottis and glottis, and the attendant exhaustion and hectic. It may occasion a fatal issue by inducing any one of the several affections I have described above (§ 569, *et seq.*) as contingent upon the administration of mercurial preparations. When the corrosive preparations of mercury have been administered, death is generally the consequence of the local corrosive action, of the disorganization caused by them, when taken in large quantity. If this effect is not produced, or is recovered from, they may still cause death from their consecutive effects now described.

538. I. *Of the Physiological Action of Mercury.*—All the preparations of mercury are more or less readily absorbed and carried into the circulation; but it is not ascertained in what state they are absorbed, or by what particular channel, although the lymphatic and lacteal vessels are most probably the chief media. In whatever state the mercurial may be when it has arrived in the blood, it evidently accumulates there, and in the solids, to some extent, especially in some constitutions or conditions of the frame, producing, among others, the effects above described. Having arrived in the circulation, it is carried out of the system, either without deposition or accumulation in the solids, or after having been for a time thus deposited, by means of the several emunctories, more especially by the salivary glands, the skin, the pancreas and liver, the intestinal canal, and kidneys. When the mercurial, owing to either the modes of administration or inaction of the emunctories, accumulates in the blood, the tissues may be so saturated with it as to give rise to the changes described, or to admit of the detection of it in the excretions, or even in the structures themselves. In whatever state it may exist in the blood, it is so intimately combined with this fluid as to escape detection by the ordinary tests, and destructive distillation is generally required. By this means it has been detected by ZELLER, BUCHNER, SCHUBARTH, COLSON, DIETRICH, and others. In the same way mercury has been found in the *secretions* and *excretions*, in the saliva, the perspiration, the urine, the intestinal secretions, and even in the discharges from ulcers, as shown by CHRISTISON, PEREIRA, and the writers just named. Dr. PEREIRA remarks, that the blackening of the skin mentioned by HARROLD, RIGBY, and others, as having occurred from the use of mercury after the employment of sulphur, shows the presence of mercury in the cutaneous transpiration. The sulphur and the mercury having been thrown out of the system by the skin, and beyond the sphere of the vital power, had en-

tered into union and formed the black sulphuret of mercury, which was deposited on the integument in a pulverulent form. The existence of mercury in the *reguline state*, in the organic solids, has been asserted by some and denied by others. WIDMER, COLSON, DIETERICH, PEIREIRA, and others say that it has been found in this state in the bones, brain, synovial capsules, the pleura, the humours of the eye, the cellular tissue, &c. In what part of the system reduction is effected is not ascertained, or whether it has occurred during life or after death. I have seen the mercury in the fluid state in bones which have been long in contact with the surrounding earth, and have viewed the reduction as a *post-mortem* phenomenon; but it may have been otherwise.

589. Mercurials, having been carried into the circulation, and even to some extent into the tissues and organs, as they undoubtedly are more or less, certainly affect the states of organic nervous and vital power, changing not merely dynamically, but also otherwise *altering* the innervation of the several organs and structures. The *alterative influence* is displayed, and can be estimated only, by its results, by the effects just described. But in addition to the altered state of general innervation, and chiefly as a consequence of it, the *blood* evinces marked changes. If salivation be easily produced, the blood either shows no very material change at the commencement, or it exhibits merely a slight inflammatory crust. But after salivation has continued some time, the blood becomes darker, coagulates less firmly, and the proportion of the coagulum to the serum diminishes. If salivation be protracted, the red globules decrease in number very remarkably, and *anæmia* is often very considerable, and always supervenes when salivation is either excessive or protracted. DIETERICH says that the electrical condition of the blood changes from the negative, the healthy state, to the positive state. With this change in the blood the soft solids are impaired in their vital cohesion, and all the exhalations and secretions from surfaces and mucous follicles are increased. The heart and lungs are also more or less affected, as Sir B. BRODIE has shown, although more as respects their organic nervous energy, or state of innervation, than as regards the structure. The *structural changes* produced by mercury have been chiefly observed after death from acute poisoning by the corrosive preparations, and have been described above (§ 218).

590. *K. Treatment.*—When the symptoms are those of *acute poisoning* (§ 216), then the treatment recommended for that form should be adopted with promptitude and activity (§ 221); but the varieties of *chronic poisoning* by mercurials require very different measures.—*a. Salivation*, when either excessive or prolonged beyond the intentions of the physician, is that variety which most frequently calls for aid, the means most successful in removing it being also the most beneficial in the treatment of the other varieties of chronic mercurial disease. The patient should be removed to a large, airy, dry, and moderately cool apartment, about 60° Fahr., and entirely apart from those who are subjected to a mercurial treatment. All the linen should be frequently changed, and vicissitudes of temperature avoided. Thus circum-

stanced, the remedial means may consist of three classes, which may be distinguished as the *antidotal or constitutional*, the *derivative*, and the *local*, which may be successively or contemporaneously employed, or in such succession and combination as the peculiarities and form of the mercurial disorder will suggest.

591. (*a*) The *constitutional and antidotal means* are limited; but, such as they are, they should not be overlooked; for, as the injurious effects of mercury, in any of the forms noticed above, often depends upon the actual presence of mercury, in some noxious state, in the circulation, and even in the tissues, and not infrequently upon the irritation this mineral causes in the several emunctories concerned in eliminating it from the system, it is important to resort to such means as are the most likely, by combining with it in the blood and tissues, to render it less deleterious, or even inert. There is probably no substance which may be more beneficially employed with this intention than sulphur, inasmuch as it is readily carried into the circulation, and as readily combines with mercury, whose injurious operation it thus prevents, the sulphuret of mercury being either inert, or nearly so. *Sulphur*, therefore, should be given internally, while *sulphur baths*, both warm and fumigating, or as either may suit the peculiarity of the case, may also be called into aid. Formerly the *sulphurets* were given internally for the removal of excessive salivation, but they are very much inferior to the simple precipitated sulphur, and are now employed chiefly in warm medicated baths. Next to the internal use of sulphur may be mentioned the diluted *sulphuric acid*, taken in quantity sufficient to render the drink pleasantly acid; but in cases of very long protracted salivation, or when anæmia has supervened, neither it nor any of the other acids, whether mineral or vegetable, has appeared to me to be of any service, unless combined with an oxide of iron. In these circumstances the sulphate of iron may be taken in small doses, dissolved in the drink acidulated with the sulphuric acid, or the citrate of iron may be given in fluids containing the citric acid. In treating most of the injurious effects of mercury, the local mischief, in whatever form it may appear, attracts the chief notice, and to it chiefly, and not to the states of the blood and of vital power, which are of the greatest importance, are our remedial measures directed. Various other constitutional means have been recommended; but there are comparatively few which deserve adoption. The most serviceable are the preparations of sarsaparilla; those of iodine; the iodide of iron, and some other combinations of iodine with sarza; the decoction of cinchona, or the sulphate of quinine with sulphate of iron, or common alum, or with the citrate of iron, according to circumstances, or to the amount of debility or of anæmia. In most of the remote or consecutive states of poisoning by mercury, and more especially in mercurial cachexia and affections of the skin, and mercurial periostitis, the iodide of potassium and other preparations of iodide, with sarza, &c., will prove most beneficial.

592. (*b*) The *derivative measures* which are most serviceable are purgatives and warm baths, and these are serviceable chiefly when salivation has occurred suddenly or unexpected-

edly; when it is recent, and the patient not much reduced. In these circumstances, the best purgatives are the neutral sulphates dissolved in the compound infusion of roses, to which some additional sulphuric acid, and small doses of the sulphate of iron, may be added; these may be administered at intervals, so as to keep up an action on the bowels, or a full dose of precipitated sulphur may be taken at bedtime, and the saline aperient in the morning and at midday if it be required. Warm medicated baths may likewise be used, or pediluvia. If constipation continue, or become obstinate, other more active purgatives may be required, if a recourse to purgative enemata does not accomplish fully the object entertained.

593. (c) The *local means* should have reference to the state and stage of salivation, and of the other symptoms. If salivation be commencing; if it be acute; if it have occurred unexpectedly, or from a small dose of mercury, and be attended by an inflammatory state of the mouth or salivary glands, the topical remedies ought to be soothing, and the local excitement should be calmed by means of demulcent gargles, containing cooling and anodyne substances, as the nitrate of potash, or the hydrochlorate of ammonia, with extract or tincture of opium; or by gargles containing the acetate of lead and acetic acid, with tincture or wine of opium. If the swelling and tenderness around the salivary glands be considerable at the commencement, a few leeches, followed by fomentations, may be prescribed, and the other means assiduously employed. In the more chronic or atonic stage or state of salivation, the gargles should be astringent and tonic, as the decoction of cinchona, or of oak bark, with alum and sulphuric acid, or with the tincture of krameria. The chlorides, especially the chloride of lime in solution, with creasote; solutions of the chloride of zinc, or of the nitrate of silver; the tincture of myrrh in camphorated demulcents, &c., may severally be employed as gargles. I have seen strong tar-water of great service when used as a gargle, a weaker form of it having been drank as a constitutional remedy.

594. (d) The *other varieties of chronic poisoning* by mercury are benefited most by the constitutional or antidotal means advised above (§ 591). But, in these varieties, the states of the blood and of nervous energy should receive particular attention. In order to remove the existing depression of vital power, to improve the assimilating processes, and to resist the changes in the blood, especially the progressive anæmia, the iodide of iron in sirrup of sarsaparilla, the several preparations of iron, or the mineral chalybeates, in states of combination which the peculiarities of the case will suggest, and many of the usual vegetable or mineral tonics and antispasmodics, will prove of essential service. When the nervous system, or even when the mental manifestations betray disorder, the means just mentioned, preceded or attended by the constitutional treatment above recommended (§ 591), are then also required; change of air and scene, travelling, a dry, bracing air, generous but light diet, aided by occasional recourse to tonics, to chalybeates, to the iodine, and to the natural mineral waters, being also beneficial.\*

595. vi. STRAMONIUM—THORN-APPLE—*Datura Stramonium*.—Poisoning with this plant is not infrequent, and is generally accidental. But the thorn-apple has been used on the Continent for the purposes of aiding the commission of crimes. The whole plant is probably poisonous, but the seeds are the most virulent. It is very slightly irritant, its poisonous action being exerted chiefly on the brain and nerves of sensation. Its operation nearly resembles that of belladonna. The active properties of the plant reside chiefly in an alkaloid principle, described by GEIGER and HESSE, and named *daturia* or *daturium*; and probably partly in an empyrenematic oil which it contains, resembling that of digitalis. It acts chiefly by absorption, and probably also by its local influence or impression on the nervous systems; for the application of the leaves of the plant to burns or sores has occasioned dangerous effects.

593\*. a. The *symptoms* produced by stramonium have been most accurately observed and described by Dr. PEREIRA. In *small and gradually increased doses*, it impairs sensibility, thereby alleviates pain, and hence is *anodyne*. Although it allays pain, it does not usually produce sleep. Dr. PEREIRA remarks that it has no direct tendency to induce sleep, and hence it *cannot be called soporific*; but indirectly, by alleviating pain, it often disposes to sleep. It usually does not affect the pulse: it slightly and temporarily dilates the pupil, and has no tendency to cause constipation, but rather relaxation. In *larger doses* it causes dryness of the throat, thirst, nausea, giddiness, dilatation of the pupil, obscurity of vision, headache, nervous agitation, disturbance of the cerebral functions, perspiration, occasionally relaxation of the bowels, and sometimes diuresis. In *fatal doses* the chief symptoms are flushed countenance, delir-

remedy and as a poison, supersedes additional matter on the subject; yet on a topic so prolific in relation to a mineral remedy, the use of which has for near a century past been so extensive in the hands of the faculty of American physicians, an additional observation or two may be made. In specific febrile disorders, it is well known that OGDEN, of Long Island, and DOUGLASS, of Boston, had recourse to mercury before its use for those purposes was made in Great Britain. In the mercurial practice for yellow fever, as it prevailed in Philadelphia in 1793 and in subsequent years, and in New York in 1795, 1798, and in 1803, as adopted by the medical men of that metropolis, great opportunities occurred of noticing the action of this powerful agent in a disorder of acknowledged specific character; while the abuse of mercury in syphilitic diseases has been the theme of repeated remark and of professional notoriety by American prescribers. The reader will do well, on all these subjects, to peruse the valuable volume on the mercurial practice of the United States by the late Dr. JOHN WARREN, of Boston. See, also, the *Massachusetts Medical Communications*, vol. ii. On this most interesting subject, the use and abuse of mercury, a work of clinical value appeared so long ago as in 1811, entitled a *Dissertation on Mercury*, by JOHN W. FRANCIS, New York. This elaborate essay contains many details of value relative to the medical history and curative action of this heroic prescription. The author considers the several forms of mercurial erethism as more likely to occur from the external applications of the remedy than from its internal use. He notices the loss of memory for years, arising from the too free introduction of mercurial salts into the system; and ingeniously contends that mercury as a curative agent effects its great design by its universally stimulating or exciting action, and its alterative influence in eliminating specific disease by unlocking all the emunctories of the body. The recent doctrines of LIEBIG, now so popular, seem to have been fully broached in this treatise by Dr. FRANCIS. The assimilating principle in elucidation of the action of small-pox, venereal disease, &c., gives unquestionably a comprehensive view both of the action of animal poison as a taint, while a like doctrine of the corrective influence of certain remedies unfolds a lucid theory of their therapeutical action.]

\* [The elaborate exposition which our author has given of the various disordered changes induced by mercury, as a

ium—usually maniacal—dilatation of the pupil, dryness of the throat, loss of voice, difficulty of deglutition, hot, perspiring skin, convulsions, and sometimes palsy. But the symptoms vary in different cases with the dose, and the part or preparation of the plant administered. Of the numerous instances of poisoning by this plant, the following will suffice to illustrate the symptoms :

594\*. In two cases related by VICAT and SWAINE, the chief symptoms were furious delirium and palsy of the extremities. In three instances adduced by ALIBERTO there were delirium, restlessness, constant incoherent talking, dancing, and singing, with fever and flushed face. In a case described by Dr. TRAILL, about eighteen grains of the extract were taken by mistake, and were followed by dryness of the throat, giddiness, dilated pupils, flushed face, glancing of the eyes, incoherence, resembling intoxication, and incessant, unconnected talking, like that of demency. Emetics were given without effect, and little amendment was obtained from blood-letting, cold to head, or purgatives. But after a glass of strong lemonade vomiting took place, and the patient soon recovered. BOERHAAVE states, that a man gave the powder of stramonium in coffee to a female. It occasioned redness of the features, delirium, nymphomania, loss of speech, followed by fixedness of the eyes, tremours, convulsions, and coma; afterward tetanic spasm and slow respiration. She was with difficulty roused by the action of emetics, and recovered. In another dangerous case, adduced, among others, by Dr. CHRISTISON, free blood-letting effected a speedy cure. Of a case well described by Mr. DUFFIN, the symptoms were exactly as above stated (§ 593\*). One hundred of the seeds were swallowed; but, although the treatment was judicious, death took place in twenty-four hours. Of several cases adduced by GÆLIN, six hours were the shortest duration. [It is not uncommon to observe hemiplegia with spasmodic affections of the opposite side in children who have eaten the seeds or flowers. I recently attended a child, a boy twelve years of age, who was poisoned by inhaling the aroma from the leaves that had been bruised in the sun. After exposure to these fumes for a considerable period in a hot sun, he was seized with maniacal, wild, hysterical delirium, contracted pupil, &c., and, in spite of treatment, died in about twelve hours. On dissection, the blood was found fluid, the brain congested, the other organs natural. For many cases of poisoning by this plant, see my edition of GUY'S *Med. Jurisprudence*, p. 697.]

595\*. *b. Diagnosis.*—VOCHE says, that stramonium is distinguished from belladonna by its affecting more the ganglia, spinal cord, and brain; by the circumstance of the pulse being little affected by it, and by slowness more frequently than acceleration of pulse being produced by it; and by its exciting the organic nervous system more strongly, and more directly promoting all the secretions, especially those from the skin. Its operation may be briefly characterized as slightly irritant and energetically alterative as regards sensibility and innervation, while it influences less remarkably the irritability of muscular structures.

596. *c. The morbid appearances* consist chief-

ly of congestion of the brain and sinuses, especially in those cases which terminate early with maniacal excitement and determination to the head. When life has endured for eighteen hours or upward, the congestion within the cranium is less remarkable. In Mr. DUFFIN's case, the brain was healthy, and not congested. The stomach and intestines were natural. There were a slight redness over the pharynx, larynx, and upper third of the gullet, thickening and swelling of the rima glottidis, and a semi-coagulated state of the blood.

597. *d. The treatment* should consist chiefly of vascular depletions; the cold or tepid affusion on the head; emetics or the stomach-pump; lemonade drinks; and the other means advised for *belladonna* (§ 545).

598. CLASS VII. NARCOTICS, OR STUPEFYING POISONS. — HYPNOTICS. — Several substances have been classed as narcotics, although they are not directly or really narcotic or hypnotic, and produce this effect only contingently upon their anodyne or sedative action—not infrequently as a consequence of the vital depression or exhaustion which they occasion in a large dose. This error of arrangement, so intimately allied to inaccurate views as to the operation and effects of both medicines and poisons, has been perpetuated by most writers on juridical medicine. But it is of great importance, in a practical rather than in a theoretical point of view, that substances which are simply *anodyne*—which remove pain or paralyze sensibility—should be distinguished from those which exert a more extensive effect, and are *sedative*—which lower nervous and vascular excitement, and depress vital action; and that those substances which are simply *hypnotic*—which merely procure sleep—should also be distinguished from *narcotics*—which do more than procure sleep, which stupefy the senses and occasion a state of lethargy, into which the patient lapses immediately after having been momentarily and with difficulty roused. There is no doubt that several substances produce effects so complicated as to render classification founded on these effects most difficult; that there are some which are not only anodyne, but also sedative or depressing, and withal both hypnotic and narcotic; and it is hence the more difficult to arrange them. Still the difficulty should be met; and, by careful observation, the more prominent effects of these substances should be recognised and assigned to each. I have had occasion to show that several substances which have been classed as narcotics are not actually such, but occasionally manifest more or less of this effect merely as a consequence of the vital depression they produce when taken in excessive doses.

599. The operation of narcotics was once a source of dispute between the chief supporters of the medical doctrines adopted toward the close of the last century. The term *narcotic*, being applied substantively and adjectively to medicines which have the power of stupefying and impairing the energy of the nervous system, the mode in which this power was excited became the subject of inquiry. As most narcotics have a stimulating influence in small doses, and as the narcotic effect is produced chiefly, or only when they are given in full or large doses, the question was, as to the way in

which this latter effect was developed. CULLEN contended that the stimulating effect is owing to the resistance offered by the *vis medicatrix nature* to the sedative influence of the substance; and hence that a large dose is immediately sedative, because this resistance is overpowered. BROWN, on the contrary, maintained that narcotics are in reality highly diffusible stimuli, which exhaust the excitability by the rapidity of their action. Thus CULLEN regarded them as directly sedative, and indirectly stimulant; and BROWN as directly stimulant, and indirectly sedative. The discussions connected with this subject, which may be viewed as constituting an epoch in the history of medicine, are now nearly forgotten, although the topic is not altogether destitute of practical importance. If both doctrines were closely investigated, neither would be found correct; but it is sufficient that we attend to the effects, and observe them correctly. The exact modes in which they are brought about require too minute an investigation to be entered upon at this place.

600. i. CARBONIC ACID GAS, and *Admixtures of it with other Gases*.—This is the most important of the deleterious gases. It is, as Dr. CHRISTISON remarks, the daily cause of accidents; for it is extricated in great quantity from burning fuel, during the calcination of limestone or chalk, by the fermentation of beer, and in pits, mines, wells, &c. It is generated during respiration by all animals, and is accumulated to a dangerous amount in apartments where due ventilation is neglected. Owing to these and other sources, being such as admit of the accidental and intentional operation of this gas on the human subject, poisoning by it is of frequent occurrence. Some doubts had been entertained whether it is a positive poison, or simply an asphyxiating gas. But, independently of its action, when concentrated or pure, in irritating and constricting the larynx, and thereby producing suffocation, it is positively and energetically poisonous. This is shown by a variety of circumstances: 1st. Poisoning by this gas is more rapid than immersion in hydrogen or azote. Immersion in carbonic acid gas will kill an animal outright in twenty-five seconds, and a small bird in fifteen seconds. 2d. If, instead of the nitrogen gas contained in air, carbonic acid be mixed with oxygen in the same proportion, symptoms of poisoning will appear in two minutes in animals which breathe this admixture. Persons have become apoplectic in an atmosphere containing carbonic acid gas in much less proportion, and which has appeared quite respirable upon first entering it. 3d. Professor ROLANDO (*Archives Gen. de Med.*, t. v., p. 132) found that the land tortoise sustained little injury when the great air-tube of one lung was tied; but instead of tying this tube, he contrived to make the animal breathe carbonic acid gas through it, and death took place in a few hours. 4th. The symptoms caused by inhaling the gas much diluted may be produced by the application of it to the internal surface of the stomach, or even to the skin. It is well known that aerated water not infrequently causes giddiness and a passing intoxication when drank too freely, especially by persons unaccustomed to it. The sparkling wines owe to this gas a portion of

their power of rapid intoxication. M. COLLARD DE MARTIGNY found that, if the human body be enclosed in an atmosphere of this gas while respiration is carried on by the common air, the usual symptoms of poisoning with carbonic acid is produced; and, if the same experiment be made on animals, death will ensue if continued long enough. 5th. It has been shown by Dr. G. BRID that death may follow the inspiration of this gas, although the usual changes are produced by the oxygen in the air on the blood, which even may still retain its florid colour (*Gov's Hosp. Rep.*, vol. iv., p. 79.)

601. A. When a person attempts to inhale pure carbonic acid gas, the throat is irritated so strongly that the glottis closes, and inspiration is impossible. Sir H. DAVY and Dr. CHRISTISON remark, that the gas causes an acid taste in the mouth and throat, and a sense of burning in the uvula; hence, when a person is immersed in this gas, he dies at once of suffocation. The effects, however, are very different when the gas is diluted, the symptoms resembling those of apoplexy or poisoning by opium, but varying somewhat according to the source from which the gas is derived, and the vapours or other gases or admixtures consequently breathed with it. It is of importance to recollect that fatal poisoning by this gas may occur where the quantity present is quite insufficient to produce much effect at first, or for some time, or to extinguish a lighted candle; and, consequently, we are authorized in concluding that a gaseous mixture, capable of extinguishing a lighted taper or candle, will almost inevitably prove fatal to animal life. No odour nor taste, also, is perceived when this gas is much diluted.

602. B. The symptoms experienced by persons exposed to an atmosphere loaded with charcoal fumes, or with carbonic acid emanating from any other source, and mixed with more or less of other gases, are well marked and constant; although, as Dr. GOLDING BRID remarks, they are far from being distinctly characteristic of the existing cause, as they are very similar to the premonitory signs of apoplexy. A person exposed to these fumes at first experiences an intense, penetrating, and throbbing headache, with a sense of weight and heat, especially about the occipital region; pulsation in, and sense of tightness across the temples; giddiness, confusion of ideas, and failure of memory; increased action of the heart, and often violent palpitations, sometimes attended by a disposition to nausea and hysterical sobbing. If the individual be now removed into a current of cool, pure air, with warm applications to the feet, which usually, in such circumstances, become cold, the symptoms gradually vanish. But if he continue exposed to the poisoned atmosphere, a buzzing noise in the ears, partial or total loss of vision, an undefined, vague feeling of intense dread or horror succeed, and are rapidly followed by somnolency or syncope. Subsequently, according to Dr. G. BRID, all power of volition disappears; the pulse, which was previously above one hundred, falls to forty or fifty; respiration becomes slow and laborious; the surface universally cold, and often livid; the lips blue or violet; the eyes retaining, in most cases, their lustre. Gradually these symptoms increase in intensity, frequently with the accession of te

tanic convulsions, and, in a few instances, raging delirium. White or bloody foam appears before the mouth and nostrils, vomiting takes place, and the sufferer sometimes expires in the act; but he as frequently breathes his last without vomiting, and, in this case, the tongue is protruded, or firmly clinched between the teeth. He is usually found in a calm and sleep-like attitude, the countenance always retaining a placid expression, which even the vomiting, that often occurs in the last moments, had not disturbed.

603. Persons who have been exposed to an atmosphere vitiated by carbonic acid gas, "until insensibility, cessation of pulsation in the smaller arterial trunks, and suspension of respiration supervene, frequently exist for a considerable time, if removed from the poisoned atmosphere, appearing partially to survive, exciting hopes too frequently fallacious; as such persons almost always sink, even after living for several days in a state of somnolence." A case, however, is recorded by Dr. BARNESON, in which a singularly judicious treatment was successful; and others have since recovered from this very dangerous state.

604. C. A small quantity of the mixed gases, proceeding from the slow combustion of tallow or oily substances, will produce dangerous symptoms. Dr. BLACKADDER ascertained (*Edin. New Philos. Journ.*, i., 224) that the vapour into which oil is resolved, previously to its forming flame round the wick, excites, even in minute quantity, intense headache. The emanations from the burning snuff of a candle are probably of the same nature, and very poisonous; and an instance of such effect is adduced by Dr. CHRISTISON. A party amused themselves by holding under the nose of a boy asleep the smoke of an extinguished candle. At first he was roused a little each time; but after half an hour, during which this was repeated, he began to breathe laboriously, and was attacked by incessant epileptic convulsions, and died on the third day. The effects of these emanations are probably partly owing to the presence of an empyreumatic volatile oil, which is an active poison (§ 668).

605. D. The admixture of sulphurous acid gas with the carbonic being inhaled in a diluted state, is extremely deleterious. When, however, the sulphurous acid gas is present in any quantity, the irritant effects produced by it, especially on the lungs and air-tubes, will often prevent accidents which might have occurred if carbonic acid gas only had been present. Instances have been recorded where the admixture of these gases have proved fatal, especially in mines. The symptoms produced by these gases, and those caused by the gradual contamination of the air in a confined apartment in which a number of living beings are enclosed, are very nearly the same, although the causes are not identical. It was found in the instances which occurred in mines, that, although the lights continued to burn, the men were poisoned; the symptoms being difficulty of breathing, pain and beating in the head, giddiness and ringing in the ears, palpitation and anxiety followed by vomiting, weakness and pains in the limbs, and, finally, loss of recollection. To these succeeded frantic delirium in some, terror in others, and insensibility in the rest. Many

retched and vomited. In some the pulse was quick, in others it was slow; in many irregular, and in all feeble. (*See Edin. Med. and Surg. Journ.*, xiii., 353; xxxii., 345.)

606. E. *Appearances of the dead Body.*—a. *Externally*, these vary with the circumstances of particular cases; but the surface is generally sprinkled with livid spots, often bluish or reddish brown, passing into violet; and these are most numerous in the most depending parts. The limbs are in some cases very flexible, in others as rigid. The fingers are often irregularly bent, sometimes stiff and extended. The arms are occasionally thrown across the chest, especially if spasms have preceded death. Opposite statements have been made as to the persistence of the animal heat, and as to the rapid or slow development of decomposition. The tongue is found projecting, and often clinched between the teeth, unless vomiting preceded death, and then it is usually in its natural position. The mouth is often covered with a white or bloody foam. The face is in some cases red and bloated, in others pale and placid. The eyes generally retain their vivacious aspect; they are sometimes injected. The pupils are dilated. The features are always in a state of repose. The interior of the nostrils, in some instances, are lined with a black, fuliginous deposit. The abdomen is distended with air. (Dr. G. BIRD.)

607. b. *On dissection*, the coverings of the head are found injected with blood. The vessels of the dura mater, arachnoid, and pia mater, as well as the sinuses, are found turgid with blood; and serous effusion often exists beneath the arachnoid. The surface of the brain is always injected, often reddish; occasionally the cerebral substance is somewhat softened, and presents the appearance of recent inflammation. The lateral ventricles generally contain fluid, sometimes limited to one side; and serous effusion is met with at the base of the brain. In addition to this congested state of the brain and cerebellum, extravasation of blood is found in a few instances; in one case, universal effusion of blood between the arachnoid and pia mater, and extending to the cerebellum; in another, into the lateral ventricles. Dr. G. BIRD states that the blood found in the cerebral vessels is black in some cases, and florid in others; and even black in some vessels, and florid in others, in the same case. Occasionally the blood is fluid, and very thick; in others remarkably thin, and in some coagulated. Effusion of reddish serum into the *pleura* and *pericardium* is frequent. The *lungs* are sometimes expanded, and full of air and blood; in others, collapsed. In many, their tint is blackish violet; in others, red, spotted with black; and in some, quite natural, and presenting merely the usual cadaveric turgescence and blackness posteriorly. The blood in their vessels is often black, sometimes florid, and even both; the vessels are frequently turgid, but occasionally nearly empty. The cavities of the *heart*, and the *blood* found in them, present as opposite appearances, in different cases, as have been described in respect of the lungs. The same remark applies to the larynx and trachea. The pharynx and oesophagus are usually healthy, and sometimes contain food, as if the patient had expired in the act of vomiting; but in the

last moments of life, the contents of the stomach are regurgitated without effort rather than vomited. The *abdominal viscera* are generally healthy, whatever lesion they present being referable to other causes. The veins are most usually congested, and more or less of serous effusion into the peritoneal cavity is sometimes seen. The blood in the abdominal veins is coagulated in some cases, and fluid in others. The *muscles* are stated to be extremely lacerable, owing to the absence of irritability of vital cohesion; but Dr. G. BIRD contends that such is not the case in some.

603. *F. The Modus Operandi of diluted Carbonic Acid Gas.*—This physician, who has paid much attention to the subject, concludes, from his researches, that an atmosphere containing carbonic acid gas will produce death, although it may contain a sufficient amount of oxygen to support life, *per se*, and to allow the arterialization of the blood to proceed. On which account, no dependence can be placed on the dark or florid colour of the blood, as arguments for or against poisoning by carbonic acid gas. He considers that this gas, when diluted, acts primarily upon the nervous system; and secondarily, but by no means essentially, upon the circulating fluid; that death is caused by the accession of apoplexy, often attended by serous effusion into the ventricles, or on the surface of the brain, and sometimes even by the extravasation of blood; and that no importance can be attached to the states of the surface, of the features, of the blood, of the limbs and muscles, and of the thoracic and abdominal muscles, as proofs of poisoning by carbonic acid gas. I need only add to this statement, that during the inhalation of this gas, or of admixtures of it with other gases, the injurious action may be produced not only through the medium of the nerves, but also by the passage of the gas itself into the circulation, where it may act more directly on the ganglionic nerves of the brain, influencing its innervation, its circulation, and vital manifestations, and thereby giving rise to the symptoms and structural lesions above described. These lesions are chiefly congestion of the vessels of the brain, with contingent serous effusion, and, more rarely, sanguineous extravasation. Beyond these, but little structural change, at least of a precise and obvious nature, is met with, either constantly or generally, although various alterations in the colour and states of both the fluids and soft solids are observed; but they are so different, or even opposite, in different cases, that no importance can be attached to them.

609. *G. Treatment.*—This should consist of cupping or general blood-letting, but cupping on the nape of the neck generally, and preferably; of an occasional recourse to cold or tepid affusions on the head and neck; of the application of derivative means to the lower extremities, and of stimulative embrocations to the chest and limbs; and of the administration of enemata, containing camphor, asafetida, with active purgatives, as turpentine, castor oil, &c. The quantity of blood which should be taken by cupping ought to be regulated by the symptoms and the progress of the poisonous effects. When these means are inefficient, owing to the existing torpor and insensibility, artificial inflation of the lungs and even re-

course to electricity, or to electro-galvanism, should not be neglected, more especially as the progress of such cases is not generally so rapid as to preclude the adoption of these means. When the temperature is much depressed, warm baths, with salt, mustard, &c., in the baths, should not be neglected. In Dr. BABINGTON'S case, decided benefit was derived from the inhalation of oxygen gas. But much will depend upon the adaptation of the various means to the states of the nervous system and of the circulation at the time of their administration. As many of the cases of poisoning by this gas are of considerable duration, sufficient time is generally afforded to ascertain the efficacy of remedies.

610. ii. *CARBONIC OXIDE GAS.*—When this gas is thrown slowly into the veins, it gives the arterial blood a brownish tint, and induces, for a short time, a state resembling intoxication (NYSTEN). But it is certainly more deleterious than the experiments of NYSTEN would seem to indicate. An assistant of Mr. HIGGINS, after inhaling this gas two or three times, was seized with giddiness, tremours, and approach to insensibility, succeeded by languor, weakness, and headache. Another assistant, having previously exhausted his lungs, inhaled the pure gas three or four times, and was suddenly deprived of sense and motion, and continued insensible for half an hour, during which time he was apparently lifeless, with the pulse nearly extinct. Various means were tried for rousing him, without success; till, at last, oxygen gas was blown into the lungs. Animation then returned rapidly; but he was affected for the rest of the day with convulsive movements, stupor, violent headache, and quick, irregular pulse; and after his senses were restored, he suffered from giddiness, blindness, nausea, alternate heats and chills, succeeded by feverish, broken, but irresistible sleep.

611. iii. *CARBURETED HYDROGEN GAS—COAL GAS.*—The several species or admixtures of carbureted hydrogen gas are more or less narcotic and injurious, although much less noxious than sulphureted hydrogen.—A. Sir H. DAVY found that, when he breathed a mixture of two parts of air and three of carbureted hydrogen, he was attacked with giddiness, headache, and transient weakness of the limbs. When he breathed this gas in a pure state, the first inspiration caused a sense of numbness in the muscles of the throat; the second, an overpowering sense of oppression in the chest, and insensibility to external objects; during the third, he felt sinking into death, and the mouth-piece dropped from his hand. On recovering his senses, which happened in less than a minute, he continued to suffer for some time from a suffocating feeling, extreme exhaustion, and feebleness of the pulse. Throughout the rest of the day he was affected with weakness, giddiness, and rending headache. Colliers, however, breathe the air of coal-mines without apparent injury, although strongly impregnated with this gas; and NYSTEN found it inert when injected into the veins. Probably the concentration of the gas, or the impregnation of the air with it, requires to be carried up to a certain point before its poisonous operation is produced.

612. *B. Coal gas and oil gas*, which are mixed and variable gases, appear to be inert, or

nearly so, when very much diluted; but since their introduction for the purposes of illumination, many fatal accidents have occurred from the respiration of air contaminated with them. *Coal gas* consists of hydrogen, proto-carbureted hydrogen, bi-carbureted hydrogen, carbonic oxide, nitrogen, and carbonic acid in varying proportions. Several cases of poisoning with this admixture, owing to the contamination of a large proportion of air with it, are recorded. The *symptoms* were vertigo, cephalalgia, confusion of intellect, with loss of consciousness; nausea, with vomiting; general weakness and vital depression; partial paralysis, convulsions, and the usual symptoms of general asphyxia. In illustration of the effects of coal gas, Mr. TAYLOR adduces the following: In January, 1841, a family in Strasburg respired for fourteen hours on air contaminated with coal gas, owing to its escape from a pipe. On discovery of the accident four persons were found dead. The father and mother still breathed; but the father died in twenty-four hours: the mother recovered. An old lady and her granddaughter, who had been annoyed by the escape of coal gas during the day, retired to bed, and were found dead about twelve hours afterward. In the case of the Strasburg family, there was probably not more than 8 or 9 *per cent.* of coal gas contained in the air of the rooms, because, when the proportion is a little greater, the mixture with air becomes explosive; and a candle was burned out, and a fire burning in the stove, showing that no explosion had taken place. In the other cases, a strong snell of coal gas could be perceived when the bodies were found, though the air could be breathed. Coal gas, therefore, like other gaseous poisons, may destroy life if long respired, although it be so much diluted as not to be injurious at first, or for a short time.

613. *C. On dissection*, the appearances have been observed chiefly in the instances just mentioned. Of the five bodies poisoned by this cause in Strasburg, the *post-mortem* examination evinced a great difference in the appearances; but the chief alterations were congestion of the brain and its membranes, remarkable engorgement of the pia mater, and intense redness of the whole surface of the brain. In three of the cases there was an effusion of coagulated blood on the dura mater of the spinal canal. The lining membrane of the air-passages was strongly injected; and there was spread over it a layer of thick, viscid froth, tinged with blood. The substance of the lungs was of a bright-red colour, and the blood was coagulated. In the other cases, recorded by Mr. TEALE (*Guv's Hosp. Rep.*, No. viii.), there was also congestion of the brain and its membranes, with injection of the lining membrane of the air-passages; but in these cases the blood was remarkably liquid.

614. *D. Treatment.*—The odour of this gas will generally lead to the detection of it, and to prevention of its injurious operation; but it may penetrate into dwellings and apartments in a very insidious manner; and if this takes place where persons are asleep, the results may be fatal in a few hours. The exact proportion of this gas to the air respired which will destroy life has not been ascertained; but from 7 to 12 *per cent.* of this gas in air will most like-

ly be sufficient, as this proportion has killed rabbits and dogs in a few minutes. Indeed, a quantity a little below the explosive proportion, or 7 or 8 *per cent.*, may be sufficient. The treatment where poisoning has taken place is the same as I have advised for the effects of carbonic acid gas (§ 609).

615. iv. CHLOROFORM.—*Perchloride of Formyle*—*Chloric Ether*, and *Ether Vapour*.—I have already made mention of *ether vapours* (see § 322, 336–340) in connexion with their effects as an *intoxicating* and *paralyzing* or *anæsthetic agents*. I shall now notice them as powerful *hypnotics* or *narcotics*, their hypnotic operation being the most speedily developed, and the most remarkable of known substances. When the effect of sulphuric ether as an anæsthetic agent was first ascertained, the advantages to be derived from it in surgery and midwifery were certainly over-estimated, and the dangers contingent on a recourse to it were not always admitted or even recognised. It certainly could not have furnished entire satisfaction to Dr. SIMPSON, who was among the most zealous in recommending it in obstetric practice, otherwise he would not have sought for another anæsthetic agent; and he was successful in finding one still more energetic, and probably more safe. [We know not how to reconcile these two qualities. In proportion to the energy of the article is its danger, unless properly used. This is especially the case with chloroform, as experience has fully proved. We cannot, from present experience, therefore, justify its use as an anæsthetic agent, especially in natural labour, which is safer in proportion as it is a *natural* process.] But a few months of trial of the sulphuric ether inhalation was thus followed by the discovery of the advantages of inhaling *chloroform*. In February, 1847, Mr. JACOB BELL first employed chloroform, or perchloride of formyle (*Pharmaceut. Journ.* for February, 1847, p. 357), as a substitute for sulphuric ether, as an anæsthetic or hypnotic agent; and in November, 1847, Dr. SIMPSON, apparently unacquainted with Mr. BELL's recommendation, had recourse to it for the alleviation of the pains of parturition. That chloroform, even in small quantity, poured upon a sponge or handkerchief, and held to the nostrils, produces the most profound sopor and insensibility in a very short period—from a few seconds to a very few minutes—cannot be disputed; and that it may be employed in surgical operations and in midwifery, so as to prevent any painful sensation, has been already shown on numerous occasions. It has likewise been proved that it is more rapid and certain in its effects than sulphuric ether, and even more safe, thus admitting that the latter is not always quite harmless. [We cannot subscribe to the truth of this remark; we believe that facts show directly the reverse. We have now more than twenty fatal cases on record from the use of chloroform, in the short period since its introduction (March, 1848).] I have already pointed out the dangers attendant upon even a prudent recourse to sulphuric ether inhalation, especially in the parturient process (§ 337, 338), and I have no reason to infer that the danger is much reduced by the employment of chloroform. Time and close observation will decide as to the amount of benefit or of mischief which may result from the use of this

latter. That it may be applied to injurious, to poisonous, and even to felonious purposes, may be anticipated from the facility of its administration, and from the communications respecting it which were instantly made to all the daily and weekly papers in the kingdom. All these hypnotic or anæsthetic agents, if breathed for too long a time, without such intermissions in their administration, or without such precautions as a prudent physician will adopt, may be followed by the most dangerous effects, in respect both of the constitution of the blood and of the nervous masses, especially the brain and medulla oblongata. Time and observation have not yet been sufficient to show the results as to chloroform; but a recourse to it should be made with caution, as an effect so potent as it produces cannot be undergone without some risk in certain states and constitutions. At the moment of writing the above, experiments made and published by Mr. T. WAKLEY (*Lancet*, January 1, 1848) demonstrate the poisonous operation of chloroform and the ethers when inhaled by the lower animals, and the following case was published by Dr. GULL.

616. A boy aged eleven, in good health, but his nervous system a little weakened by confinement to bed, his heart and lungs sound, was about to have the flexor tendons of the knee-joint divided in Guy's Hospital, and chloroform inhalation was adopted. "A small quantity of chloroform, not exceeding thirty drops, was put upon a cone of bibulous paper, and placed over his mouth and nose. In less than a minute he was entirely insensible, the pupils becoming widely dilated, and the pulse small and frequent. As the operation was being proceeded with, his consciousness partly returned, and a few drops of the chloroform were put upon a handkerchief and applied to the nose. He was instantly affected, and to such a degree that there was the greatest apprehension of his never rallying. The pulse was very feeble, 56; the breathing so indistinct as hardly to be distinguished; the face pale, lips congested; the symptoms of collapse extreme. Ammonia was employed, and, after about five minutes, he gave two or three deep inspirations: it was, however, more than fifteen minutes before he was out of danger. Subsequently a small quantity of brandy was administered. He complained of headache. For a long time after he recovered his special senses and power of motion, general and perfect anæsthesia of the surface existed. The following day he was quite well." (*London Med. Gaz.*, December 10, 1847, p. 1036.) The above case sufficiently illustrates the injurious action of this substance; and, in the present state of our knowledge and experience of the inhalation of this and other preparations of ether, it is unnecessary to make any farther observation.

617. v. *CICUTA VIROSA*—*Water Hemlock*.—This indigenous plant has sometimes produced accidentally the most noxious effects. The roots and the rest of the plant are poisonous, but the roots especially. Among other instances related by WEFER, eight children ate the roots instead of parsnips. Two of them died. The first symptoms in these two were swelling in the pit of the stomach, vomitings, or efforts to vomit, total insensibility, involuntary discharge of urine, and, lastly, severe spastic convulsions. One died in half an hour, the other

soon after. One who recovered had convulsions, followed by deep coma, from which she could not be roused for twenty-four hours.—*a.* According to GUERSENT (*Dict. des Sciences Méd.*, t. v., p. 205), the first symptoms of poisoning with *cicuta* are dimness of sight, vertigo, acute headache, pain in the stomach, anxiety, dryness of the throat, thirst, and vomiting; followed by enuresis, epileptic convulsions, lethargy, and insensibility, in some cases; and by delirium, unconsciousness, or convulsions, with tumefaction of the face, protrusion of the eyeballs, &c., in others.

618. *b.* On dissection, METZDORF met only with congestion of the blood-vessels of the brain and its membranes. GUERSENT, in addition to congestion of the cerebral vessels, mentions flaccidity of the parietes of the heart's cavities, and congestion of the lungs and liver with a dark fluid blood. The body is sometimes swollen, the abdomen distended with air in the intestines, and the surface covered with livid spots. But the only changes which are constant are the congestions now mentioned. The same treatment as recommended for *belladonna* (§ 545) or *opium* (§ 657) is required for poisoning with this plant.

619. vi. *CONIUM*—*Hemlock*—*Conium Maculatum*—*Conia*.—This plant may certainly be viewed as the *κόνειον* of Greek writers—the celebrated *Athenian state poison*, by which SOCRATES and PHOCION died—the *cicuta* of the Romans. NICANDER states that this plant brings on obliteration of the mental faculties, dimness of sight, giddiness, staggering, stiffening, coldness of the limbs, and death by asphyxia. "A view of its effects," says Dr. CHRISTISON, "which differs little from the modern notions of the poisonous action of the spotted hemlock." Dr. PEREIRA adds, that the ancients regarded *κόνειον* as having the power of discussing tumours—a virtue which has been assigned to hemlock by writers of the present day. The effects of conium upon animals and upon man are somewhat different, the action on the former more closely resembling that of its alkaloid, *conia*.

620. *A. Symptoms.*—*a.* In small doses it produces but slight or hardly manifest effects. But it sometimes causes, when long continued, disorder of the digestive organs or nervous system, dryness of the throat, thirst, and occasionally the reduction of swellings or of tumours, and an eruption on the skin. If the dose be gradually and much increased, the effects are often more severe; delirium, syncope, or coma supervening. The ancients believed that hemlock exerted a specific influence over the mammæ and testicles, preventing the development of the former, and causing wasting of the latter, especially in girls and boys respectively. The Arabians entertained similar ideas. These effects have even been imputed to it in modern times.

621. *b.* In large or poisonous doses the symptoms indicate a dangerous affection of the cerebro-spinal system. In some of the best-recorded cases, coma was the prominent symptom, the effects being similar to those of opium. In other instances, convulsions or violent delirium, or both, were prominent. A soldier had partaken, with others, of a soup containing hemlock leaves, and soon afterward fell asleep. In the course of an hour and a half his comrades

became alarmed on finding themselves affected with giddiness and headache; and the surgeon was sent for. He found the soldier who had fallen asleep in a state of insensibility, from which, however, he could be roused for a few moments. His countenance was bloated, tumid, and bluish; the pulse only thirty, and the extremities cold. The insensibility increased until he died, three hours after taking the soup. Two cases are described by Dr. WATSON, which were fatal in the same short period. Giddiness, coma, and convulsions were the principal symptoms. When the dose is not sufficient to prove fatal, there is occasionally paralysis attended by slight convulsions. Sometimes there is frantic delirium.

622. *B. Conia, conicin, cicutinc*, or the alkaloid of conium, in which the active properties of the plant chiefly reside, exists in it in combination with an acid—the *conicic*? Its effects are known only by experiments on the lower animals. On them it acts as a powerful paralyzing agent; affecting first the muscles of voluntary motion, then the respiratory muscles of the chest and abdomen, lastly the diaphragm, and thus producing death by asphyxia (CHRISTISON). Convulsive tremours and twitches of the limbs are also sometimes observed. Dr. PEREIRA remarks, that “the primary seat of the action of the *conia* is probably the spinal cord (probably also the medulla oblongata and brain).” “In this *conia* and *strychnia* agree; but in the nature of the effect, as Dr. CHRISTISON has observed, they are the opposites of each other. *Conia* exhausts the nervous energy of the cord, and causes muscular paralysis; *strychnia* irritates it, and produces permanent spasm of the respiratory muscles.” These effects of *conia* suggest its employment in convulsive and spasmodic diseases.

623. *C. On dissection*, the chief alterations which are observed are congestion of all the vessels within the cranium, and a very fluid and dark state of the blood. In a case examined by Drs. CHRISTISON and COINDET, the vessels within the head were not particularly turgid, but the blood was everywhere remarkably fluid. Death in this case was produced in an hour, by two ounces of a strong infusion of hemlock leaves with the same quantity of whiskey, which was swallowed in the morning, fasting, at the suggestion of one of those meddling persons who are so very kind in prescribing for their acquaintances that of which they know nothing. The symptoms in this case were coma and slight convulsions. The fluidity and dark hue of the blood are merely the results, as Dr. CHRISTISON suggests, of the asphyxia, which is the proximate cause of death in poisoning by conium. The same treatment as is recommended for *belladonna* (§ 545) or for *opium* (§ 657) is appropriate for the effects of conium.

624. vii. HENBANE—*HYOSCYAMUS NIGER*—*Hyoscyamia*, &c.—All parts of this plant are poisonous, especially the seeds and roots. They produce somewhat different effects upon animals and upon man, being more hypnotic in the former than in the latter.—*A.* In small doses they are calming, sedative, and slightly narcotic. Mr. HOULTON has shown that their effects vary much with the age of the plant, the season at which the several parts of it are gathered and prepared, and the mode of preparation

and preservation. Large doses sometimes procure quietude and sleep, but with no certainty; for they not infrequently occasion dimness of sight with dilatation of the pupil, headache, giddiness, and a state of half-sleeping and half-waking, with a tendency to delirium. In some cases, thirst, nausea, clamminess of the mouth, feverishness, griping and relaxation of the bowels, are induced. Very large doses much more frequently produce delirium than sound sleep. In poisonous doses it causes loss or disturbance of vision, dilatation of the pupil, coma, with muttering delirium, distortion of the features and loss of speech, paralysis, with irregular convulsive movements, and occasionally violent delirium, and irritation of the stomach and bowels, with vomiting, griping, and purging.

625. *B.* The special effects of *hyoscyamia*, the alkaloid in which much of the active properties of the plant are believed to reside, have not been fully shown. Dr. MORRIS has ascertained that, like other narcotic and sedative vegetables, as opium, hemlock, tobacco, stramonium, digitalis, &c., *hyoscyamus* also yields by destructive distillation an *empyreumatic* oil of great activity; its poisonous properties depending upon a volatile principle which is not essential to the oil, and is productive of coma, convulsions, and speedy death.

626. *C. Hyoscyamus*, especially its juice and extract, is most actively poisonous when injected into the blood, less so when applied to the cellular tissue, and still less when taken into the stomach. It is sometimes very active when administered in an enema. It has even produced serious effects when applied to the sound surface in the form of a poultice. WILMER was called to a lady affected with sopor, dilated pupils, flushed face, loss of speech, full pulse, and swelling of the abdomen, and found that these symptoms were caused by a poultice of henbane leaves applied over the abdomen to relieve strangury. It acts chiefly on the brain, and by absorption into the circulation.

627. *D. Diagnosis*.—The effects of *hyoscyamus* differ from those of *opium* in being more sedative in small doses, by the affection of the sight and dilatation of the pupils, by the much less, and more uncertain, soporific operation in large doses, and by the delirium, loss of speech, and paralysis, with irritation of the bowels, in poisonous quantities. *Hyoscyamus* differs from *belladonna* and *stramonium* by the less frequent and less remarkable occurrence of gastro-intestinal irritation from it, and by the more manifest appearance of narcotic or soporific action. It differs also from *hydrocyanic acid* in producing delirium and paralysis, while the acid occasions insensibility and convulsion, and more rapid results.

628. *E.* The other species of *hyoscyamus*, as the *albus*, *aureus*, *physaloides*, and *scopolia*, are said to be equally poisonous with the *H. niger*. Professor FODÉRÉ states, that the *H. albus* was boiled and distributed by mistake among the crew of a French corvette. But in a short time after eating it they were all seized with giddiness, vomiting, convulsions, colic, purging, and violent delirium. They were all relieved by emetics and purgatives. The appearances in fatal cases have not been described. The treatment is the same as in other cases of narcotic poisoning.

629. *Lactuca virosa*, *L. sativa*, and *Humulus lupulus* are not likely to occasion dangerous effects from accident or otherwise.

630. viii. OPIUM AND ITS PREPARATIONS.—MORPHIA AND ITS SALTS.—The operation and effects of opium have been investigated by numerous able inquirers, but most satisfactorily by CHRISTISON, PEREIRA, and CHARVET. Since 1821, when I first resorted to the cold affusion in the treatment of poisoning by opium, I have devoted much attention to the medicinal and poisonous properties of this substance, probably the most valuable of all the articles of the materia medica.

631. A. The local action of opium is exerted chiefly on the nerves of the part, more especially on the sentient nerves, but the irritability of contractile tissues is also affected. When a watery solution, or fluid extract, of opium was applied to a painful part, or to a surface denuded of its cuticle, I found that the morbid sensibility was removed in the one case, and numbness caused in the other; and that the intestinal movements were arrested by the application of the same preparation to the mucous surface of the intestines. This latter result was also remarked by Dr. W. PHILIP. Dr. MUNRO found that opium injected into the cellular tissue caused palsy of the hind legs of a frog. Several physiologists have shown that, when opium is applied to the internal surface of the heart of a frog, this organ ceases to beat.

632. B. The remote effects of opium have been fruitful topics of discussion. It was formerly believed that the impression made by opium upon the nerves of the stomach, or of any other part, is conveyed sympathetically to the brain; but it has been conclusively proved that the poison itself enters the circulation, and acts directly either upon the brain or upon the ganglia and ganglionic nerves supplying the brain and its blood-vessels; this latter alternative appearing to me the most probable. (See § 654, *et seq.*) According to ORFILA's experiments, the action of opium is most energetic when injected into the veins. Opium is more active when applied to a wound than when taken into the stomach; and it often acts, when thrown into the large bowels, with as much energy as when taken by the mouth, and sometimes even more energetically. Much, however, of the effect produced by it, when thus administered, depends upon the state of the large bowels, as respects fecal accumulations, &c., upon the period of its retention, and the mode of its exhibition.

633. a. It has likewise been shown by ORFILA and others, that a large dose of opium affects the lower animals somewhat differently from man, causing in the former accelerated circulation, vertigo, palsy of the hind legs, convulsions, varying from tremors to violent spasms, and a wakeful kind of slumber, attended by convulsions upon the least excitement; while in man simple sopor and coma are most commonly produced, and convulsions much less frequently. According to CHARVET's researches, opium acts as a poison to all animals, when given in a large dose; and on the lower animals it produces congestion of the brain and consequent sopor, irritation of the nervous centres and convulsions, and a directly sedative effect on the muscles.

634. b. The effects of opium in the human sub-

ject are of great importance in a practical as well as in a toxicological point of view. In small doses, opium acts at first as a stimulant of the heart and arteries, causing also a slight exhilarating effect upon the mind, and sense of fullness in the head. A pleasurable state of the whole system is experienced, and a capability of greater exertion. These symptoms are followed, in about two hours, by a diminution of muscular power and of susceptibility to the impression of external objects, and by a desire of repose with tendency to sleep. The mouth and throat generally become dry, thirst is increased, desire of food is impaired, and costiveness produced. These effects are much diminished by frequent repetition, and an increase of the dose is required to produce them in an equal degree.

635. c. In a larger dose, or full medicinal dose, or from two to four grains, the stage of excitement is sooner followed by depression. Dr. CRUMPE (*Inquiry into the Nature and Properties of Opium*, 8vo, 1793, p. 85) took two grains and a half of opium when his pulse was at 70. After a quarter of an hour his pulse rose to 74, and after half an hour to 80. After fifty minutes the pulse had fallen to 64; but in an hour and a half it returned to 70. With the acceleration of the pulse, the skin becomes hot, the mouth and throat dry; thirst is increased, and the appetite diminished. But the symptoms of excitement are soon followed by indisposition to exertion, by sluggishness of the senses, confusion of ideas, and an irresistible desire to sleep, which is generally attended by dreams, sometimes pleasing, at other times frightful. Upon waking, especially if three or four grains have been taken, nausea, or even vomiting, headache, furred tongue, listlessness, and costiveness are complained of; but the accession of these may be prevented by repetitions of the dose, and by even a gradual diminution of it. Dr. BURNES states, that he had made a very fatiguing night march in India with a Coutehee horseman, and assented to his proposal of halting for a few minutes, which he employed in sharing about two drachms of opium between himself and his jaded horse. The effect of the dose was soon evident on both, for the horse finished a journey of forty miles with great apparent facility, and the rider became more active and intelligent.

636. C. The poisonous effects of opium, or the symptoms of poisoning, where opium is given in a single dangerous dose, begin with giddiness and stupor, generally without any previous excitement. The stupor rapidly increases; the person becomes motionless, and insensible to external impression; he breathes slowly, generally lies quite still, with his eyes shut and his pupils contracted, occasionally remarkably contracted; the cornea is dull, or no longer glistening, and the whole expression of the countenance is that of repose. In this stage he may be slightly or momentarily roused by violent excitement, as pinching, &c. As the poisoning advances, the features are ghastly, or slightly livid; the pulse feeble and irregular; respiration shallow, slow, or gentle, and sometimes catching; the muscles exceedingly relaxed; and, lastly, the pulse becomes remarkably slow, unequal, and irregular, and death rapidly ensues, if assistance is not promptly administered.

ed. If recovery takes place, the sopor is succeeded by prolonged sleep, which is followed by headache, giddiness, nausea, and vomiting, loathing of food, distressing languor, and constipation.

637. *D. OPIUM EATING.*—*The excessive use of opium, habitually,* produces a species of slow poisoning, of so long duration as not to be generally viewed as poisoning, although the effects are allowed to be injurious. The habit is usually acquired by persons who have derived advantage from opium in various states of disease, especially painful affections, hysteria, diarrhœa, and numerous other disorders. The habitual opium eater may be instantly recognised by his appearance; by the emaciation of his body; by a withered, yellow, or sallow countenance, and sunken, glossy eyes; and by the bending of the spine and lame gait. His digestive functions are remarkably impaired, his appetite is lost, and he hardly eats. He scarcely has more than one evacuation in the week. As the habit becomes more confirmed, his strength diminishes, and the craving for the stimulus becomes even greater; and to produce the desired effect, the dose must constantly be augmented. The mental and bodily powers are ultimately destroyed, and a universal impotence is the last result.

638. I have met with in practice several instances of opium eating, in which the symptoms were less severe. In these, however, although the quantity taken was excessive, the appetite was not materially, or even at all impaired; and the bowels were often regular, unless when deprived of the usual dose of the opium. The pulse varied from 80 to 100; and the skin was occasionally dry, but more frequently perspirable, or perspired very freely. The effect produced by a desired ordinary dose upon the mental faculties of the opium eater is usually described as that of calmness, comfort, serenity, and happiness; and a capability of supporting mental exertion and bodily fatigue.

639. When deprived of this substance, the opium eater is miserable and distressed; and the whole frame betrays the want of it, by the hollow, dark, and sunken orbits; by the haggard appearance of his features; the general weakness and tremulousness, especially of the hands; by the dry and parched state of the mouth and throat, anxious voice and manner, and by loss of appetite and sleeplessness. Many thus affected are anxious to abandon the practice, and make numerous efforts to accomplish it, but they rarely succeed.

640. If the habit be commenced early in life, the person who is its subject seldom becomes older than forty years; and he may die at an earlier age, if the practice has been excessive. When the quantity of opium taken habitually is comparatively moderate, when it is not increased in quantity or frequency of dose, but little injury to the general health often appears for many years; and even an improvement of the health is often remarked when the practice has originated in the use of opium for painful affections, obstinate diarrhœa, certain states of hysteria, &c. Several persons thus circumstanced have been under my care for various disorders, and they described themselves in better health than before the acquisition of the habit. But in most of these the quantity was

not remarkably large, and was generally not materially augmented. But in others, who take very excessive quantities, either of laudanum or solid opium, and still more remarkably in those who do not confine their indulgence to opium, but have recourse also to other intoxicating beverages to excess, visceral disease slowly and silently supervenes, with its usual consequences; the constitutional powers sink, and death sooner or later takes place. I have thus met with organic diseases of the liver and stomach, of the heart and kidneys, palsy, and tubercular phthisis slowly appear, and ultimately terminate in dropsical effusions, which treatment could not control. I lately attended a gentleman, a graduate of Cambridge, of most Herculean frame, with my friend and former pupil, Mr. PYPER. That gentleman took habitually the largest amount of opium that I have heard of having been taken by one person; but, not content with this, he indulged also in several bottles of wine in the course of the day, and sometimes in strong ale and in spirits. Although scarcely above thirty years of age, his powerful constitution and frame were broken down, his liver was enlarged, and dropsical effusions had supervened.

641. *E. OPIUM SMOKING* is rarely practiced in Europe. But it is not infrequent in numerous countries in the East; and it is the favourite mode of intoxication in China. Dr. PEREIRA has collected most instructive accounts of this practice. MARSDEN states, that the *smokable extract* is made into pills about the size of a pea. One of these being put into the small tube that projects from the side of the opium pipe, that tube is applied to a lamp, and the pill being lighted, is consumed at one whiff or inflation of the lungs, attended by a whistling noise. The smoke is never emitted by the mouth, but by the nostrils, and sometimes, by adepts, through the passage of the ears and eyes. Mr. SMITH, surgeon, of Pulo Penang, states that, although the practice is most destructive to those who live in poverty and distress, or who carry it to excess, yet it does not appear that the Chinese in easy circumstances, and who have the comforts of life about them, are materially affected, in respect of longevity, by the private addiction to this vice. It would appear that, as in *opium eating*, so in *opium smoking*, a moderate addiction to the habit is not attended by remarkable injury to the constitution; and that it is excess in either that is productive of injury.

642. *a.* The *first effect* on opium smokers is to render them more animated and loquacious. "Gradually the conversation drops; laughter is occasionally produced by the most trifling causes, and to these succeed vacancy of countenance, pallor, shrinking of the features, so that the smokers resemble persons convalescing from fever, followed by a deep sleep for half an hour to three or four hours. An inordinate quantity causes headache, vertigo, and nausea. The Malays are rendered outrageous and quarrelsome by the opium-pipe." It is extremely difficult to discontinue this vice; yet there are many instances of its being done. This destructive practice deteriorates the physical constitution and moral character, especially of the lower orders. Its effects on the system are manifested by stupor, forgetfulness,

impairment of the mental powers, emaciation, debility, sallow complexion, lividity of the lips and eyelids, languor and lack-lustre of the eyes, loss of appetite, sweetmeats or sugar-cane being most relished.

643. In the morning the opium smoker has a most wretched appearance, and is unrefreshed by sleep, however profound. He experiences a remarkable dryness and heat in the throat, with depression and restlessness, which incite him to have recourse to the opium pipe; and if it be not resorted to, there is great prostration, torpor, vertigo, discharge of water from the eyes, &c. If the privation be complete, coldness of the body, aching pains in various parts, feelings of bodily and mental misery, and sometimes diarrhœa, are complained of. Total privation has even been followed by death, if the habit has been long continued and excessive. A close resemblance may here be traced between the effects of *opium smoking* and *tobacco smoking* (§ 527). The latter is as injurious as the former, when as excessively practiced; and the one habit, as well as the other, occasions more or less general and sexual impotence, and entails on the offspring a weak, decrepit, and stunted growth, and a delicate and strumous constitution. How weak and debased must be the mind that, by the selfish and excessive indulgence of a petty vice, sacrifices not only his own health, but also the health and constitution of his offspring, and the ability of perpetuating his name and lineage!

644. *F. Diagnosis of Poisoning by Opium.*—The effects of this drug may be mistaken for *apoplexy* or *syncope*, or for the *stupor* consequent upon an attack of *epilepsy*, or upon *suppression of urine*. But the sopor of opium is different from the coma of these, inasmuch as the individual is capable of being momentarily roused from the former, unless death be very near, by means of pinching, tickling, brisk shaking, or loud talking. The state of restored consciousness is, however, frequently imperfect, and is speedily followed by lethargy. When convulsions attend poisoning by opium, the difficulty of distinguishing it from *epilepsy* is greater; but even then the patient may be momentarily roused, which is impossible in the epileptic paroxysm. In all the maladies, moreover, just enumerated, the pupils, in the majority of instances, are dilated or natural; and partial paralysis, or even more complete palsy, attends many cases of them; whereas in opium poisoning the pupils are remarkably contracted. Sopor from *intoxication* may be confounded with opium poisoning, but the redness of the conjunctiva, the ferrety eyes, the full and rapid pulse, and the odour of alcohol in the breath, will generally indicate the nature of the case. Poisoning by opium is not infrequent in *infants* and *children*; and it is in them very generally attended by convulsions. It is with great difficulty distinguished from *infantile convulsions*, proceeding from cerebral or other affections. Contraction of the pupil is almost the only indication of this poison having been given; the history of the case, and other circumstances which his acumen will suggest, will in some measure guide the physician. The diagnosis of poisoning by other narcotics than by opium is noticed where they are treated of.

645. *G. The quantity of opium which may be*

*fatal* will necessarily depend upon the state of the stomach and of the nervous system at the time of taking it.—*a.* During painful or spasmodic disorders, and in states of mental excitement or irritation, very large doses of opium may be taken with comparatively little effect. A lady, in a state of great excitement and irritation, took an ounce of laudanum when going to bed, with a suicidal intention; but she was surprised, on waking in the morning, at finding herself alive, with rending headache, nausea, and feeling of general disorder, from which she soon recovered, no aid having been administered. I have repeatedly prescribed, and once taken, as much as four grains; but I would not advise a larger dose to be given; and even this dose may be followed by unpleasant effects in some constitutions, especially the susceptible and delicate, and when the system is depressed or where there is a tendency to apoplexy; and even a smaller dose may be serious when administered in an enema or in a suppository. Mr. TAYLOR states that a man was killed by ten grains of solid opium; and a woman of middle age by eight grains, given in two doses. Dr. CHRISTISON says that the *smallest dose of solid opium* which has been known to have proved fatal to an adult was four grains and a half, mixed with nine grains of camphor, death having taken place in nine hours. In a case recorded by Dr. SKAE, it is doubtful whether death was caused by two or by four drachms of the tincture. A lady suffered very serious symptoms from twenty drops of the tincture administered in an enema; and Dr. STEINTHAL states that one grain of opium, in a clyster, occasioned alarming effects. Idiosyncrasy may be the cause of the danger produced by small quantities of the drug. On the other hand, recovery has taken place from very large doses, when vomiting has soon occurred or been procured by treatment, or when they have been taken on a full stomach, or in states of nervous excitement. In such circumstances even as much as four ounces of the tincture has failed to produce death, as in a case mentioned by Mr. TAYLOR. [We have attended, in consultation, a lady who died from swallowing four grains of opium in pill; and in another case, a gentleman, who recovered after taking eighteen grains of sulphate of morphia, although it had not been evacuated from the stomach. In this case the treatment was bleeding, cold to head, external revulsives, constant rousing and shaking, stimulating enema, and internal stimulants, &c.]

646. *b. Infants and children* are remarkably susceptible of the influence of opium, and instances of poisoning among them by over-doses of the preparations containing opium are very frequently met with. An instance is reported (*Lancet*, Feb., 1842) of an infant, two days old, having been killed by one minim and a half of the tincture; and that of another by two drops. A child four months old was nearly dead in consequence of having taken one tenth of a grain of opium. Less than half a grain was given to a child four years and a half old: it soon became comatose, and died in seven hours. Dr. MERRIMAN met with an instance of excessive stupor produced in an infant a month old by a single drop of laudanum; and he met with two instances of death caused by a small dose of GODFREY'S Cordial, which contains opium. Even

twelve or fifteen drops of paregoric elixir may prove fatal in an infant. In most fatal instances in children of poisoning by opium, the post-mortem examination affords little or no information; congestion of the brain and of the lungs, with fluidity of the blood, have been the chief appearances which I have remarked.

647. *H. The periods which elapse from the administration of the poison until the commencement of its effects* are various. A large quantity in the form of a tincture, taken on an empty stomach, begins to act in a few minutes. Coma seldom comes on before half an hour has elapsed. The interval is sometimes considerable, even when the tincture has been taken. Dr. CHRISTISON refers to a case where it was considerably more than an hour after two ounces and a half of the tincture and a drachm of the extract had been taken. Opium in the solid form generally requires a longer time to act than the tincture. DESRUELLES, however, records a case where two drachms of solid opium produced sopor in fifteen minutes; and in a case published in America, the largest quantity of it ever known to have been taken at once did not occasion this effect until an hour had elapsed. The interval may doubtless be prolonged if the opium be taken by a person already excited by spirituous liquors, or intoxicated. Mr. SHEARMAN relates the case of a man who, in a state of intoxication, took two ounces of laudanum, and had no material stupor for five hours; but he ultimately died.

648. *I. The period at which death takes place* varies from two hours, the shortest period, to forty-eight hours, the longest period; but most fatal cases terminate between six and twelve hours after the ingestion of the poison. Those who live above twelve hours generally recover, if they be judiciously treated. Instances, however, have occurred where an apparently efficacious treatment has been too soon suspended or relinquished, owing to appearances of rapid recovery, and a relapse has supervened and carried off the patient. In eight fatal cases of poisoning by opium, reported by Dr. BECK, the smallest quantity taken was one drachm, the largest one ounce and a half. The shortest time between the taking of the poison and death was eight hours, the longest twenty hours.

649. *K. Several preparations containing opium* have produced fatal effects, especially when administered by ignorant or careless persons to infants or children.—(a) *Paregoric elixir*, the compound tincture of camphor, which contains somewhat less than one grain of opium in half an ounce, has caused death. A child between five and six years of age was killed by a dose which contained about one grain of opium; and another aged seven months by a dose equal to a quarter of a grain of opium. See *Pharm. Journ.*, April, 1845, p. 464.—(b) *DOVER'S Powder*.—*Pulvis ipecacuanha compositus* has also been fatal to children. In one case, four grains of this powder, equal to two fifths of a grain of opium, caused death; and in another, ten grains caused the death of an infant in twenty-four hours.—(c) *Sirup of poppies* is said to contain one grain of the extract of English opium to one ounce. The common dose of it to an infant of six or seven months is half a drachm. But this should be the largest dose allowed. Owing, however, to this dose, or its equivalent

for other ages, being much exceeded, and owing to a mixture of tincture or infusion of Turkey opium, the strength of which is often variable, being substituted for the true sirup of poppies, poisoning has often occurred from this medicine. Seven children died from this cause in 1837. In a case alluded to by Mr. TAYLOR, half a teaspoonful of this sirup caused the death of an infant six months old. The narcotic symptoms were developed in three quarters of an hour. The sirup in this case was probably prepared with tincture of opium in excessive quantity.—(d) *Decoction of poppies* has not infrequently been fatal to infants. A teaspoonful of it has been fatal to a healthy child. A woman boiled two poppy heads in a quarter of a pint of milk, and gave two small spoonfuls of this decoction to her infant. In an hour the child fell into a deep lethargic sleep, the breathing became stertorous, and in ten hours it died. A maid-servant gave an infant two teaspoonfuls of a decoction of one poppy head in a small pot of water. The child was found dead in the morning. The brain and its membranes were much congested, and the ventricles contained bloody serum.—(e) Several *nostrums*, especially the "*black drop*," and BATTLEY'S "*sedative solution*," which are much stronger than the official tincture, have produced fatal effects. Mr. STREETER states that a drachm and a half of the latter was fatal to a lunatic, and 20 minims killed an old woman. "*GODFREY'S Cordial*" and DALBY'S *Carminative*," which contain a small quantity of opium, have caused, in some instances, the death of infants to whom they had been given in large doses.

650. *L. Morphia and its Salts*.—Poisoning with the salts of morphia has occurred in several instances. The *acetate* and the *muriate* of morphia have been the salts usually employed. The symptoms differ but little from those produced by opium, but spasms or convulsions are more frequently observed after morphia than after opium. The acetate of morphia has been estimated at four times the strength of pure Turkey opium; but I believe that pure morphia, and especially either of the salts just named, is five times the strength of opium. It is difficult to determine the quantity which may be injurious. I have seen one third of a grain given for the first dose produce unpleasant or even distressing effects. It singularly happened, that the lady, whose case was alluded to above (§ 645) as having taken with a suicidal intention, during extreme mental excitement, a large quantity of laudanum, and recovered from it without any assistance, and without any suspicion of the act, had prescribed for her by me, many years afterward, one quarter of a grain of the acetate of morphia, and although she had then recovered from so large a quantity of opium, this dose of the morphia produced very distressing effects, with a sense of sinking and symptoms of vital depression, requiring powerful stimulants to remove. Dr. KELSO (*Lancet*, September, 1839) suffered dangerous symptoms from having taken about half a grain of the muriate; and Mr. TAYLOR was informed that an adult was killed by three grains taken medicinally; and he adds, that there is reason to suppose that half a grain of the acetate caused the death of a lady to whom it had been given medicinally when in a state of ill

health. Dr. CHRISTISON mentions a fatal case from the ingestion of ten grains, death taking place in twelve hours, although the stomach had been completely cleared of the poison within half an hour from the time when it was taken. One fifteenth part of a grain applied *endermically*, produced severe cerebral symptoms in a case alluded to by Mr. TAYLOR.

651. The effects of either of the salts of morphia will depend much upon the state of the person at the time who takes it. A large dose, from half a grain to a grain, may be of service, or at least not injurious, even when given for the first time, in states of nervous or vascular excitement, during excessive pain, and in several spasmodic diseases; but either of these quantities may be dangerous, or even fatal, if it be given to a person morally and physically depressed, or to one possessing weak vital resistance, or in a state of marked debility and ill health. These salts should never be given to children under ten or twelve years of age. I speak generally, some exceptions being admitted among children not much below this age. The observations offered above, as to the operation of opium when administered by the rectum (§ 632), equally apply to the salts of morphia.

652. I am acquainted with seven ladies who have either lately been, or are still occasionally, under my care, and who *habitually take excessive quantities of the acetate of morphia*. The acetate is the salt which they all employ; and they all take it in solution, with the addition of acetic acid, and, in some instances, of an aromatic spirit or tincture. The quantities taken at one dose in these cases vary from two to six or seven grains, which are generally taken thrice daily. In three of these cases, the quantity has not been materially increased for eight or nine years; but during that time sundry efforts have been made gradually to diminish the quantity, but they have never been steadily persevered in, a gradual increase, and return to the larger quantity, having soon followed. The effects have not appeared in these cases materially different from those of laudanum.

653. *M. Appearances after Death by Opium or its Preparations*.—In a case of poisoning by opium in a child four years old, death having taken place in eleven hours, I found the following appearances. There was considerable lividity of the back and more depending parts of the body. The vessels and sinuses of the brain were much congested, with a dark fluid blood; and more serum than usual was found at the base of the skull, and in the ventricles. The vessels of the medulla oblongata and spinal cord, and the vertebral sinuses were remarkably engorged. The lungs were congested with fluid blood. The right cavities of the heart also contained blood. There was slight redness of the villous coat of the stomach and duodenum. In a case referred to by Dr. CHRISTISON nearly similar changes were observed in the brain and lungs; but, although the body had been kept only two days in the month of February, the belly emitted a putrid odour when opened. Congestion within the cranium, with more or less serous effusion, and congestion of the lungs, the blood being dark and fluid, have generally been observed. Dr. BRIGHT and Mr. TAYLOR met with a spot of ecchymosis on the surface of the brain in addition to unusual tur-

gescence of the vessels. Dr. CHRISTISON remarks that congestion and serous effusion are by no means universal, for in a case which proved fatal in seven hours, and which he examined, neither of these changes was very apparent. Extravasation of blood within the cranium is a rare effect of opium. In the case of a female, who died eight hours after taking two ounces of laudanum, Dr. JEWEL found several clots of blood in the substance of the brain, and one, which lay in the anterior right lobe, was an inch long. (*Lond. Med. and Phys. Journal*, February, 1816.) Redness of the stomach is by no means general, and no inflammatory changes are observed. Lividity of the external surface of depending parts is commonly observed, and is owing to the fluid and dark state of the blood. But the blood is not always fluid, at least in all parts of the body. It is chiefly, however, in the cavities of the heart where it has been most frequently found coagulated. In four cases referred to by Dr. CHRISTISON there were clots found in both ventricles. This physician has particularly noticed the rapid passage of the body into putrefaction, both in cases which have come under his own observation, and in those recorded by others. Of a body, which had been kept only thirty hours in a cool place in December, the cuticle easily peeled off, and the joints were flaccid, an acid smell being exhaled. In other cases, the early progress of putrefaction has been observed, but not constantly or even generally. The poison may sometimes be found in the stomach, or its smell may be detected; but as frequently neither can be detected, especially when a considerable time has elapsed before death has taken place, owing to the absorption or partial digestion of it, or to its discharge by vomiting or the stomach-pump. In the latter case, the opium may be detected in the matters evacuated from the stomach.

654. *N. Modus Operandi of Opium*.—That the active and odorous principles of opium are absorbed is proved, 1st, by the opiate odour being often perceived in the breath of persons who take opium, and, according to BARBIER, in the perspiration and urine; 2d, by the narcotic influence of the milk on infants when the nurses have taken opium: this I have observed on several occasions; and, 3d, by the assertion of BARREAU, that he has detected morphia in the blood and urine, after the ingestion of large doses of opium; but this requires farther proof. That the effects of opium upon the frame are due chiefly to the absorption of it, is shown by the following circumstances: The effects produced by the injection of opium into the veins are the same in kind, but more intense in degree, as those which follow the administration of it by the mouth; and the constitutional effects produced by the drug are proportionate to the absorbing powers of the surface to which the drug is applied. The effects of opium are, 1st, *primary and local*; 2d, *secondary and remote*.

655. *a. The direct or local action is on the nerves*, as already shown (§ 631). It most probably excites or stimulates the nerves primarily; but this influence is only temporary and of short duration, and is followed by anæsthesia and paralysis—by a privation of energy or power. The *remote* operation is exerted chiefly on the brain, medulla oblongata, and spinal

cord; or, rather, upon that portion of the ganglial system and nerves supplying the nervous centres, and the blood-vessels of these centres and their membranes, through the medium of the blood, either principally or altogether; or partly, also, by the propagation of the direct or local impression or influence produced by the drug. That the remote effects are produced upon, or by means of, that portion of the ganglial system supplying the large nervous centres, and consecutively upon the brain, rather than upon the brain more immediately and independently of this part of the ganglial system, is indicated by the fact of the structure of the brain being itself as insensible of, and, as far as our senses enable us to judge, as little influenced by irritants applied to it, as is the structure of any other secreting organ—of the liver, kidneys, &c., as well as by various other considerations and analogies, and more especially by what is known or presumed of the functions of the ganglial system.

656. *b.* As to the nature of the effect thus produced upon the nervous system, upon the ganglial and the cerebro-spinal, it may be inferred, with tolerable truth, to be primarily *exciting* when the dose is small or moderate, and consecutively *hypnotic*, *narcotic*, and *alterative*; but that, when the drug is taken in excessive quantity, the exciting operation is not recognised, while the consecutive effects are most prominent and intense; the alterative effect, however, being evinced chiefly in cases of chronic poisoning by opium, by opium eaters and opium smokers, and where opium in any form or dose is taken frequently for a long period. The *proximate cause of death* by opium may be referred partly to the extreme congestion of the brain and medulla oblongata caused by it, and partly to the gradual extinction of the influence exerted by the ganglial system upon the cerebro-spinal centre. Most probably the depression or exhaustion of this influence causes the congestion, which, in its turn, aggravates and ultimately extinguishes the influence of this part of the ganglial system; or, the presence of the poison in the blood of the cerebral vessels may so congest them, by depressing the energy of the ganglial nerves supplying them, as to paralyze the brain, and gradually arrest all the functions more immediately depending upon the cerebro-spinal system. According to either of these views, which differ but little from each other, the paralysis of sensation and motion—the extinction of consciousness and volition—is soon followed by paralysis of the respiratory movements; and asphyxia, with its usual results—congestion of the lungs, and a dark and fluid state of the blood—is the manner in which death takes place.

657. *O. Treatment of Poisoning by Opium, or its Preparations.*—The obvious intentions are, 1st, to remove the poison as promptly as possible; and, 2d, to counteract and remove the effects which have been produced, and prevent the accession of others.—*a.* The stomach-pump should be resorted to as speedily as possible, and the stomach completely emptied and washed out by means of it. When the stomach has power to act, emetics may be employed. The best emetics are the sulphate of zinc, mustard mixed in water, or a strong solution of salt; but, in order to excite the paralyzed stomach

more completely, camphor and capsicum may be given with the sulphate of zinc, this last being administered in a dose of half a drachm or two scruples, which may be repeated in a short time if the first dose fails to act. When the stomach-pump is not at hand, a long tube, or a catheter with a bladder attached to it, as advised by Mr. BRYCE, may be substituted. After the stomach has been filled with warm water from the bladder, the tube is to be turned down so as to act upon the contents of the stomach as a siphon. When emetics are inoperative, and the stomach-pump or its substitute cannot be obtained, then it has been recommended to inject tartar emetic in the veins; but more than a grain should not be ventured on, and care must be taken not to allow the introduction of air. This, however, is a hazardous practice and seldom required, when the means already, and those about to be advised, are duly employed.

658. *(b)* The removal of the lethargy already produced by opium is best accomplished by affusion of cold water on the head and neck, as first recommended, and its effects illustrated, by Mr. WRAY and the author. (*Sec Lond. Med. Rep.*, xviii., 26.) Children may be placed in a warm bath, to which mustard is added, and the cold affusion on the head momentarily adopted. In all cases, the cold affusion should not be continued too long at a time, but employed at intervals, or with the return of the lethargy. It will often be found that, when emetics have been given without effect, owing to the paralyzed state of the stomach produced by the narcotic, the cold affusion will have the effect of rendering them sufficiently operative, especially if the fauces are tickled with a feather at the same time, or soon after the affusion has been employed. Other means of rousing the patient should not be overlooked, and may be resorted to in the intervals between the affusion. Flagellation on the palms of the hands, on the feet, or back; making the patient to walk between two assistants; stinging with nettles, pinching, &c., have severally been found of more or less service. Various internal excitants may be exhibited, as asafetida, ammonia, musk, capsicum, camphor, and may even be administered in enemata; and various exciting odours or vapours, as those of ammonia, aromatic vinegar, may be held at intervals near the nostrils. If these means fail, electricity, galvanism, or electro-galvanism may be adopted. [We have found galvanic magnetism the most important agent in the treatment of narcotic poisoning.] As death is evidently proximately caused by asphyxia (§ 656), artificial respiration should be resorted to in extreme cases, especially if the case is too far advanced to be benefited by cold affusion, or when this latter fails, which, however, will rarely occur, if judiciously employed. Frictions over the chest, with stimulating embrocations, with camphor, ammonia, capsicum, &c., will be found to aid the influence of artificial inflation of the lungs. Instances have been published by Dr. WARE, of Boston, United States, and Mr. WHATELEY, of the good effects of artificial respiration in almost hopeless cases of poisoning by this drug.

659. *c.* The subject of *antidotes against the effects of opium* has been examined by ORFILA, and he has found all those which have been

proposed at various times quite unsuccessful as long as the poison still remains in the stomach, the only exception being the decoction of galls. When the poison has been as completely removed as possible, camphor, green tea, and strong coffee have been found of service in keeping the patient awake, or in reviving him, and are suitable aids to the cold affusion, or even to the tepid affusion, when the coma is not profound.

660. *d.* As to the propriety of prescribing *local* or *general blood-letting* in cases of poisoning by opium and other narcotics, it may be remarked that cases will occasionally present themselves in which, at some period of their progress, either the one or the other may be practiced with advantage. When the patient is plethoric, young, and strong; when there is stertorous breathing, with other symptoms of congestive apoplexy; and when the countenance is bloated, the eyes injected or suffused, then general or local blood-letting, especially the latter, and preferably by cupping on the nape or on the mastoid processes, to a considerable amount, will generally be most beneficial. But before vascular depletions are prescribed, the evacuation of the poison should be attempted or procured. In a case detailed by Dr. YOUNG (*London Med. Gaz.*, vol. xiv., p. 655), of the United States, about thirty ounces of blood were taken from the arm at three bleedings; cold was applied to the head and sinapisms to the legs, and the patient recovered, although an ounce of laudanum, in a teacupful of whiskey, had been taken and remained upon the stomach. In cases which admit of doubt as to the propriety of blood-letting, advantage will be derived from *dry cupping* on the nape. I have prescribed it in one case of poisoning by opium with success. During the coma produced by this drug, or by other narcotics, the loss of a small quantity of blood often produces serious depression. Therefore depletions of every kind should be cautiously employed, and not be attempted unless the breathing is stertorous, puffing, slow, and regular, and the pulse still possesses some degree of power. The effect of either bleeding or dry cupping will be greatly aided, and the necessity of having recourse to either frequently superseded by a due recourse to the *cold affusion*, which generally prevents the distressing headaches, and other cerebral and nervous symptoms, usually experienced for some days after recovery, when it has not been employed.

661. ix. SULPHURETED HYDROGEN GAS.—NYSTEN found that a few cubic inches of this gas caused almost immediate death with convulsions when injected into the veins, although at once absorbed by the blood; and that the same quantity was almost as rapidly fatal when injected into the cavity of the chest. Similar results were obtained when it was injected into the cellular tissue, or even when left for some time in contact with the sound skin. According to THENARD and DUPUYTREN, air impregnated with the 1500th part of this gas kills birds in a short time, and with the 800th part soon kills a dog. CHAUSSIER found that in a moderate quantity it was quickly fatal, whether it was inhaled or injected into the cellular tissue, stomach, or rectum, or simply applied to the skin. Nine quarts of the gas thrown into the

rectum of a horse killed it in one minute; and a rabbit whose skin was exposed to it died in ten minutes. (CHRISTISON and SEDILLON'S *Journ.*, xv., 28.) Dr. CHRISTISON and Dr. TURNER found that it appeared to cause in plants a state analogous to narcotic poisoning in animals.

662. *A.* The *symptoms*, in cases where the vapours, consisting of an admixture of those of ammonia with this gas, such as they exist in the pits of the Parisian necessaries, as described by HALLÉ and others, are those of extreme vital depression and of asphyxia, and often terminate fatally in a very short time. If the person be but slightly affected, he complains of nausea and sickness; his skin is cold, his respiration is regular, the pulse is frequent, and the muscles, especially those of the chest, are affected with spasmodic twitchings. If he be more severely affected, he becomes soon deprived of sense and motion; the surface is cold, the lips and face assume a violet tint, the lips are covered with a sanguineous mucus; the respiration is hurried, laborious, and convulsive; the pulse is small, weak, irregular, and hurried; and the muscles and limbs are relaxed. If still more intensely attacked, death either takes place immediately, or, in addition to these symptoms, there are violent twitchings of the muscles or violent spasms. When the person is sensible after exposure to these vapours, he often complains of severe pains, and the pulse is very frequent and irregular. If the symptoms are very severe, recovery rarely takes place.

663. Instances of poisoning by sulphureted hydrogen unmixed with other vapours or gases, are not of frequent occurrence. Mr. TAYLOR states that the men excavating the Thames tunnel suffered severely from the presence of sulphureted hydrogen, which he found both in the air and in the water. The gas issued in sudden bursts, so as to be at times perceptible by the odour. By respiring this atmosphere, the strongest men were in the course of a few months reduced to a state of extreme exhaustion, and several died. The *symptoms* with which they were first affected were giddiness, sickness, and general debility. They became emaciated, and fell into a state of low fever, accompanied with delirium. (*Op. cit.*, p. 623.)

664. In the more *acute states* of poisoning with this gas, the symptoms vary with the concentration of the poison. When breathed in a moderately diluted state, a sense of weight or oppression is felt at the epigastrium and in the temples, with giddiness, nausea, sudden weakness, and sinking, soon followed by a loss of sensation and motion. If removal to a pure air be effected immediately upon the occurrence of these symptoms, and if stimulants, the cold affusion, a moderate depletion, and other suitable means be employed, life may be restored. If, however, the patient remain but a short time unassisted, and especially if the gas be breathed after insensibility has taken place, recovery is almost hopeless. When the air contains less of this gas, and the respiration of it continues for some time, vital depression, pains through the frame, convulsions or spasms, delirium, coldness of the surface, laborious respiration, a weak and irregular pulse, followed by coma and tetanic spasms or convulsions, are the prominent symptoms. "When the air is only slightly

contaminated with this gas, it may be breathed for a long time without producing any serious symptoms." Sometimes there is nausea or sickness, with pains in the head or in the abdomen: these are often complained of by persons engaged in chemical manipulations with this gas. Sulphureted hydrogen is readily absorbed into the blood, to which it gives a brownish-black colour.

665. The admixture of this gas with other gases and vapours render them remarkably deleterious. Probably a small portion of it exists in the noxious emanations disengaged from cess-pools, privies, drains, &c. The presence of it in all such emanations is well shown by exposing to them a piece of filtering paper moistened with a solution of lead. Dr. CHRISTISON remarks, that the smell alone should not be relied upon, as putrescent animal matter exhales an odour like that of sulphureted hydrogen, though none be present. This gas may be so abundant as to prove quickly fatal where lights burn with unimpaired brilliancy; and in places where it is apt to accumulate, the contamination by it may vary so much as to render the air either unrespirable in a few minutes after it has been respired without risk, or respirable soon after fatal effects by it.

666. *B. The Appearances after Death.*—A highly offensive odour is exhaled from all the cavities of the body, and, if inhaled into the lungs of the persons making the inspection, unpleasant symptoms, chiefly syncope, or even asphyxia, are occasioned by it. The mucous membrane of the nose and fauces is covered by a brownish viscid mucus. The muscles are of a dark colour, have lost their contractility, and are insusceptible of the galvanic stimulus. The lungs, brain, and liver are congested with black fluid blood. The right cavities of the heart are also congested with fluid black blood. The body rapidly undergoes putrefaction. When polished silver, or white-lead, is introduced into the cavities or under the skin, it soon becomes blackened. The treatment of poisoning by sulphureted hydrogen, or by admixtures of it with other gases or vapours, is the same as that recommended for the effects of carbonic acid gas and its admixtures. (See § 609, *et seq.*)

667. CLASS VIII. NARCOTIC AND IRRITANT POISONS—NARCOTICO-ACRID POISONS—ACRO-NARCOTICS.—The designations of this class of poisons indicate their operation. Certain of these substances are injurious in consequence of their irritating rather than of their narcotic action; while others produce a more prominent narcotic than irritant effect. Some, and probably most of them, conjoin with these modes of action more or less of a vitally depressing or exhausting operation. Owing to the effects of these poisons being thus complex, and more especially to either of their effects being more prominent than the others, these poisons have been variously classed, but chiefly as narcotics, or as irritants, or as acro-narcotics; and in this last category I now consider them. I shall, however, notice only those which are most likely to prove poisonous owing to their possession of these properties in a marked degree.

668. i. EMPYREUMATIC OILS.—The empyreumatic oil of tobacco, and of various other *poisonous plants*, are active poisons. Several other empyreumatic oils are used in medicine which

act powerfully as stimulants and antispasmodics, and which are more or less injurious when administered in excessive doses. The chief of these are, oil of amber, oil of wax, beech-oil, DIPPEL's animal oil, the oil procured by the destructive distillation of lard, &c. Dr. CHRISTISON states that this last oil, when freed of adhering acid by rectification from quick-lime, is limpid and very volatile, has an insupportable smell, and diffused in the air it irritates the eyes and nostrils, and occasions giddiness. BUCHNER found it to possess narcotic properties when its vapour was inhaled; but it is less powerful when taken into the stomach, although it then causes symptoms of irritation and insensibility. An instance of poisoning by the oil of DIPPEL, or the rectified empyreumatic oil of hartshorn, is mentioned by CHAUSSIER, who states that the person took a spoonful by mistake, and died almost immediately. No morbid appearances could be detected in the dead body.

669. ii. FOOL'S PARSLEY—*Æthusa cynapium*—has occasioned serious accidents owing to its resemblance to parsley. Professor FICINUS discovered in it an alkaloid soluble in water and alcohol, but not in ether. Mr. STEVENSON (*Lond. Med. and Phys. Journ.*, xiv., 425) has recorded the cases of two ladies who ate of this parsley in a salad, and were soon afterward seized with nausea, vomiting, headache, giddiness, somnolency, pungent heat in the mouth, throat, and stomach, difficulty in swallowing, numbness in the limbs, tremours, and frequent startings. Dr. CHRISTISON mentions the case of a child, recorded by GMELIN, that died in eight hours after having eaten the *æthusa*. The symptoms were spasmodic pain in the stomach, swelling of the belly, lividity of the surface, and difficult breathing. In two children who recovered, complete insensibility, dilated insensible pupils, staring of the eyes, and in one vomiting, in the other convulsions, were the prominent symptoms. The treatment consisted in the administration of milk, sinapisms to the legs, and cold sponging with vinegar.

670. iii. FUNGI, POISONOUS.—POISONOUS MUSHROOMS.—Poisonous mushrooms and the effects produced by them have been fully discussed by FODÉRE, ORFILA, DE CANDOLLE, ROQUES, GREVILLE, CHRISTISON, and others, to whose works I must refer for many interesting details, and for the characters which distinguish the several poisonous species from the edible.—A. The poisonous species enumerated by ORFILA are the *Amanita muscaria*, *alba*, *citrina*, and *viridis*; the *Hypophyllum maculatum*, *albobitrium*, *tricuspidatum*, *sanguineum*, *cruza-melitense*, *pubibundum*, and *pellitum*; the *Agaricus necator*, *acris*, *piperatus*, *pyrogalus*, *stypiteus*, *annularis*, and *urens*; and to these may be added *Agaricus semiglobatus* and *campanulatus*. It is probable that other species are also injurious, or may become injurious owing to season and other causes about to be noticed.

671. Numerous circumstances influence the properties not only of those which are ascertained to be injurious, but also of those which are esculent. Climate, season, soil, and manure, age, or period of the year when they are gathered, cooking and drying, severally change the properties of both the poisonous and esculent species; and in certain constitutions and idiosyncrasies even the latter class disagree

and are more or less injurious, causing diarrhœa, nausea or vomiting, colic, somnolency, &c. It is even believed that the best mushroom, when taken in too large a quantity, or too frequently, or for too long a time, are deleterious. The writers mentioned above (§ 670) have given general directions for distinguishing the wholesome from the poisonous species; but these cannot be relied on, for the former may become injurious owing to the circumstances just stated, and to others not fully recognised or explained, if their appearances be not duly observed. Much of the unpleasant effects produced by them has been owing to the carelessness of the collectors who have gathered some of the poisonous species, as well as of the esculent species, when they have become old or sickly, and mixed them with those which are wholesome. This is not infrequently the case when mushrooms are gathered from the fields for the manufacture of catsup. The surest tests of deleterious fungi are, an astringent, styptic, hot, or pungent taste, and a disagreeable pungent odour, an orange or rose-red colour, or a blue tint soon after being cut; and the circumstances of their growing in tufts or clusters from the stumps or trunks of trees. The poisonous properties of fungi have been supposed to reside in a certain principle which has been called *fungin*, but its nature and physical properties are imperfectly known.

672. *B.* The symptoms produced by poisonous fungi vary from those of extreme irritation of the gastro-intestinal mucous surface to those of fully-developed narcotism; but generally they are an association of both classes, either predominating in different cases. A man ate by mistake several of the *Agaricus campanulatus*, but, before ending his repast, and not above ten minutes after he began it, he was attacked with dimness of vision, debility, giddiness, trembling, and loss of recollection. On obtaining assistance his countenance expressed anxiety; he reeled about, and could hardly articulate; his pulse was slow and feeble. He soon became so drowsy that he could hardly be kept awake. Vomiting was produced by sulphate of zinc, and he gradually recovered. (*Lond. Med. and Phys. Journ.*, xxxvi., 451.)

673. Several soldiers ate a quantity of the *Amanita muscaria*. In the evening, some hours afterward, they began to complain of anxiety, a sense of suffocation, frequent fainting, burning thirst, and severe gripes. The pulse became small and irregular, the body bedewed by a cold sweat, the features changed, and the nose and lips of a violet tint. To these supervened tremblings, tumefaction of the abdomen, and a profuse fetid diarrhœa. The extremities became cold and livid, the pain of the abdomen intense, delirium and coma took place, and death followed. In the former case, the symptoms were those of narcotic poisoning; in the latter, those of irritation and vital depression. In other instances the symptoms are those of gastro-intestinal irritation, conjoined with narcotism, or with narcotism and extreme vital depression.

674. Six persons ate carp stewed by mistake with the *Amanita citrina*. Three of these had vomiting, followed by deep sopor, but recovered. One had violent cholera, but recovered also. Two (children) became profoundly le-

thargic and comatose; emetics had no effect, and death soon ensued. Six persons ate a quantity of the *Hypophyllum sanguineum*, and from twelve to thirty hours after the poisonous meal they experienced pain in the stomach, a sense of impending suffocation, and violent efforts to vomit. To these were added sopor, and several hours afterward tetanic spasms and convulsions; other severe symptoms, varying in character with the quantity which had been taken, also supervening in the progress of the cases. In one, profound lethargy and general coldness of the surface; in another, vomiting, bloody stools, and yellowness of the skin; in a third, delirium, tremblings, coma, and convulsions; in a fourth, loss of speech and severe dysentery; and in a fifth, colic and inflammation of the bowels, without diarrhœa. Those who recovered remained long in a state of delicate health.

675. Dr. CHRISTISON ascribes the tardiness of the approach of the symptoms in some cases to the indigestibility of most of the fungi, which in some instances is so great, that portions of them have been discharged by vomiting as late as fifty-two hours after they were swallowed. But this slowness of operation is not generally observed, for the effects sometimes appear in a few minutes. The most immediate effect produced by poisonous fungi is paralysis of the vital actions of the stomach, the symptoms afterward appearing with a rapidity in proportion to the development of the morbid action. An important characteristic of poisoning by mushrooms, as this physician has remarked, is the great durability of the symptoms. Even the narcotic effects of some fungi have lasted above two days; and ORFILA has adduced instances in which the gastro-intestinal irritation has continued from a fortnight to three weeks after the more acute symptoms had subsided.

676. When wholesome mushrooms disagree, owing to idiosyncrasy, the symptoms are chiefly those of severe indigestion, following upon, and often continuing a considerable time after, an attack of vomiting and purging. "There is some reason for suspecting that even the best mushrooms, when taken as a principal article of food for a long time, will prove injurious," and induce a peculiar depraved habit of body, leading to external suppuration and gangrene. Dr. CHRISTISON adduces from Rust's *Magazine* an instance of a family who were seized with an intermittent fever, and an eruption on various parts of the body, of abscesses which discharged a thin, ill-conditioned pus, passed rapidly into spreading gangrene, and proved fatal to two persons. No other cause could be assigned for the concurrence of these symptoms in six persons in one family, than the circumstance of their having lived for two months almost entirely on mushrooms, the only person who escaped having merely slept in the house, but had his food where he worked.

677. Dr. CHRISTISON has directed attention to a fact, of which medical men should be aware, that poisoning may be, and actually has been, perpetrated by the intentional admixture of vegetable or mineral poisons with wholesome mushrooms; and that when the murderer is dexterous in the choice and mode of administering the poison, such cases may readily escape suspicion, and, even when suspected, might not

cleared up without difficulty. But in these cases the only decided proof of poisoning by some other substance mixed with mushrooms, or with preparations of them, is the actual discovery of another poison.

678. *C. The Appearances in fatal Cases.*—The surface of the body is generally stated to be livid, and the blood to be fluid; and exudations of blood are observed from the natural openings. The digestive canal is distended by fetid air, and in some cases presents inflammatory appearances, passing in places to gangrene. The stomach, unless there has been vomiting or diarrhœa, often contains fragments of the poison; and these fragments may be found as late as the second or third day, either in the stomach or in the intestines. The liver is often congested. The lungs are generally gorged. The vessels of the brain and its membranes are commonly turgid. In a case referred to by Dr. CHRISTISON, the arteries, as well as the sinuses, were distended with blood; the pia mater and arachnoid were of a scarlet colour, and the substance of the brain was red. The choroid plexuses were excessively gorged; and a clot of blood as large as a bean was found in the cerebellum.

679. *D. Treatment.*—Dr. CLENDINNING, in a learned and interesting lecture on poisonous fungi (*Lond. Med. and Surg. Journ.*, vol. vi., p. 168), remarks, that the remedies recommended by NICANDER consist chiefly of emetics and wine. Horseradish and mustard are among his vegetable means. White vitriol is also advised by him; and for drink or vehicles for solid medicines, oxyerate and wine. The first object is to effect the expulsion of the poison; and as there are no poisonous substances of equal power that take so long a time in developing their action as fungi, so there is none against which emetics may be administered with equal prospects of advantage at advanced stages, or after so long a period from the ingestion of the poison. There is no antidote to the poison of fungi known, and hence the expulsion of them should be the chief intention. After this end is attained, the inflammatory irritation, and the narcotic and other nervous symptoms should be allayed by means appropriate to the prominent features of the affection; by the means required for gastro-intestinal irritation and inflammation, when these predominate; and by the measures recommended for narcotic poisoning when this is the prominent character, more especially by cold affusions, external derivatives, and other means suggested when treating of opium poisoning (§ 658, *et seq.*).

680. *iv. HEMLOCK-DROPWORT—Eranthe Crocata.*—ORFILA states that this plant may be mistaken for hemlock, and that a single medicinal dose of the extract taken instead of the extract of hemlock might prove fatal. The symptoms are heat in the throat and stomach, delirium, stupor, and convulsions. Dr. PICKELLS has collected thirty cases of death from eating the root. The symptoms were insensibility, delirium, and tetanic convulsions. Mr. HOWELL has mentioned eleven cases, of which two were fatal. The symptoms were chiefly convulsive, both in these and in eight others detailed by Mr. RAY. In a case described by Mr. HOUTSTON, they were at first giddiness, rapidly followed by coma and violent convulsions. In

none of the fatal cases was life prolonged beyond four hours; and in several death took place within an hour. The *post-mortem* appearances are generally slight, consisting of inflammatory redness of the internal surface of the digestive canal and congestion of the brain. Portions of the roots are sometimes found in the stomach, as in the cases of four persons who were lately killed by this poison, out of fourteen who had eaten it by mistake. (See *Lond. Med. Gaz.*, May, 1844.) The treatment is the same as in cases of poisoning by fungi (§ 679).

681. *v. GRAIN, OF VARIOUS KINDS*, is sometimes poisonous, owing to disease.—*a. Spurred rye—Secale cornutum, or ergot*—is most commonly a cause of slow poisoning, in the form of a disease which is described, according to the form it assumes, under the articles GANGRENE and SPASM. (See, also, ERGOTISM.)—*Unripe grain, spoiled grain, mouldy bread or biscuits, or grain or bread of any kind*, which has become injured from keeping too long, or otherwise, will produce disease of a chronic or slowly developed form—a true state of slow poisoning—when made a principal article of diet, or when partaken of for too long a period; and if the grain, either before or after its preparation as food, be much injured, severe symptoms may appear from having taken it at a single meal.

682. *b. The symptoms* usually produced by spoiled grain or bread are generally those of gastro-intestinal irritation, and but slightly or contingently those of narcotism; and, according to the nature and state of these articles, the symptoms may assume the form of *acute or chronic diarrhœa, or dysentery, or of scurey, or scorbutic dysentery*, under which diseases the subject is fully entertained. Grain, however, may be injurious from other causes: from the presence of the ova of insects, or of a variety of minute insects; and from the admixture of some vegetable poison, as the *darnel-grass*, or some *poisonous leguminous seeds*.

683. *vi. LABURNUM—Cytisus Laburnum.*—The bark and seeds of the common laburnum contain an active poison called *cytisin*. Dr. TRAILL met with two cases of poisoning by the seeds; and Dr. CHRISTISON has reported an instance of chronic poisoning caused by the bark, the symptoms being chiefly those of gastro-intestinal irritation, of which the patient did not recover for some months. The symptoms in Dr. TRAILL's cases were coldness of the whole surface, lividity of the face, and complete insensibility. MM. CHEVALLIER and LASSAIGNE, who discovered the active principle, *cytisin*, in the seeds, gave eight grains in four doses to a man, which occasioned giddiness, violent spasms, frequency of the pulse, and consequent exhaustion. (CHRISTISON.)

684. *vii. LEGUMINOUS SEEDS*, especially the *Lathyrus cicera* and the *Erum criliu*, or bitter vetch, have been found in France productive of chronic poisoning, chiefly in consequence of the accidental adulteration of flour with them. The symptoms have been usually weakness of the limbs, partial or complete palsy, or stiffness of the joints, and weakness and tremours of the lower extremities. They more properly belong to the class of *depressing and paralyzing poisons* (§ 261).

685. viii. *LOLIUM TEMULENTUM*, or *darnel-grass*.—The seeds of this plant are irritant and acrid, and powerfully narcotic. They have proved deleterious, and even fatal, owing to accidental adulteration of flour or grain with them. Dr. CHRISTISON states, that when mixed in bread, darnel-grass has caused headache, giddiness, somnolency, delirium, convulsions, paralysis, and even death. M. CORDIER found, by experiment on himself, that very soon after eating bread containing the flour of darnel-grass, he felt confusion of sight and ideas, languor, heaviness, and alternate attacks of somnolency and vomiting. The bread was commonly vomited soon after he ate it. SEEGER has related cases in which the somnolency was more deep, and general tremours also present. Many years ago, the inhabitants of the poor's house at Sheffield were attacked with symptoms of poisoning by porridge, which was supposed to have been made of meal accidentally adulterated by the darnel. The chief symptoms were a piercing stare, quivering of the lips, frontal headache, dilated pupil, and confusion of sight, small tremulous pulse, violent agitation of the limbs, twitches of the muscles, and palpitation. In twelve hours all those attacked were well but two, who had strong convulsions in the subsequent night; they also eventually recovered. (*Lond. Med. and Phys. Journ.*, xxviii., 182.) In some instances loss of speech and somnolency are the most prominent symptoms; while in others gastro-intestinal irritation predominates, occasioning vomiting and purging.

686. ix. *YEW-TREE*—*Taxus Baccata*.—The berries and leaves of the yew-tree are extremely poisonous, and sometimes act without either vomiting or purging. Dr. PERCIVAL states, that a table-spoonful of the *fresh leaves* was administered to three children, of five, four, and three years of age, as a vermifuge. Yawning and listlessness followed. The eldest complained of pain in the abdomen, and vomited a little; but the other two suffered no pain. They all died within a few hours of each other. Mr. TAYLOR adduces a case by Mr. HURT of poisoning by the berries of this tree. A child, aged three and a half years, ate some yew-berries, and about an hour afterward appeared ill, but did not complain of pain. It vomited part of its dinner, mixed with some of the berries. A medical man was sent for; but the child died of convulsions before he arrived. On inspection, the stomach was found to contain mucus and half-digested pulp of the berries and seeds. The mucous membrane of the organ was reddened and softened. Other instances of death by this poison are recorded, but they furnish no additional information. I believe that this poison acts as an *acro-sedative*, rather than as an *acro-narcotic*; but its effects have been very imperfectly observed.\*

687. CLASS IX. SEPTIC POISONS.—This class of poisons has been doubted, or, rather, the op-

eration of certain poisons in rapidly dissolving the vital cohesion of the tissues, to and near which they may be applied, has been disputed; and, certainly, if any one were inclined to surrender the reports of more than one of his senses to the inferences of hypothesis, to such a one may doubts of the existence of this particular action appear reasonable. It is true that the poisonous agents which are thus capable of loosening, with more or less rapidity, the cohesion of living tissues, and of disposing them to enter into different physical conditions, are few; although many possess this power indirectly, or by giving rise to a succession of morbid actions, of which a septic condition, or a state of loosened or almost entirely dissolved vital and physical cohesion, is the most advanced. These latter, however, fall not under the present category; although the rapidity with which this ultimate result is produced, as respects some of them, might countenance such an arrangement. I may, nevertheless, allude to some of these incidentally. Dr. CHRISTISON observes, when noticing this topic, that "if we were to trust the impressions the vulgar entertain of the effects of the bites of serpents, the poisons now mentioned would be considered true *septics* or putrefiants, for they were once universally believed, and are still thought by many to cause putrefaction of the living body. This property has been assigned them, probably on no other grounds than that they are apt to bring on diffuse subcutaneous inflammation, which frequently runs on to gangrene." (*Op. cit.*, p. 575.) I confess myself possessed of the vulgar belief that the local effects of the bites of serpents are not inflammatory, however this much used and abused appellation may be qualified by certain adjuncts as diffusive or diffuse, gangrenous, destructive, sloughing, phlogistic, sthenic, asthenic, dynamic, adynamic, and twenty others, employed to convey certain ideas of morbid conditions, as they may suit a theory or subserve an hypothesis. But any one who has witnessed the bite of a poisonous snake, who has seen the swelling, infiltration of the tissues, the coldness, the arrest of capillary circulation, the softening and almost dissolution of the textures, and the subsequent rapid decomposition of the part and of those in its vicinity—all which takes place in a few minutes, and is consummated in an hour or two in some instances—may not consider the word *septic* as altogether misapplied, at least until a better one is supplied, or unless we submit to a periphrasis. But the more local alterations are not the only phenomena, for the remote effects, the extreme depression of organic nervous influence, and of the vital manifestations generally, are equally rapid and remarkable.

688. The poisons which most undoubtedly belong to this class are chiefly the secretions of snakes and other reptiles, although there is reason to believe that several other secretions or morbid matters will produce analogous changes in the healthy body when inoculated with them; that the secretions from smallpox, from plague, from gangrenous sores, from glands and farcy, from erysipelatous parts, and from sloughing, gangrenous or putrid animal substances, will so contaminate the parts into which they are inserted or inoculated, as to produce either a constitutional disorder specifically the

[\* According to Liebig, no agent which does not contain nitrogen possesses a poisonous action in a small dose, and the medicinal or poisonous action of the nitrogenized vegetable principles has a fixed relation to their composition. It is evident, however, that the poisonous action is not owing to the nitrogen they contain, for *solanine* and *pirotozine*, which contain least nitrogen, are powerful poisons. *Quinine* contains more nitrogen than *morphia* and *caffeine*; and *theo-bromine*, the most highly nitrogenized of all vegetable principles, are not poisonous.]

same as that of which it is the product, or a state of local disorganization rapidly passing into vital destruction, accompanied by dangerous, and often fatal, constitutional disturbance. The inoculation of smallpox in the Negro constitution produces, in many instances, on some occasions—in the majority of cases in certain circumstances, as I have myself witnessed, a putrid or septic condition, the confluent eruption consisting of a black sanies contained in the softened dermis, which, with the circulating fluids and soft solids, rapidly deliquesce, as it were, into dissolution, before even respiration had ceased, and without any indication of antecedent excitement or unusual reaction.

689. I have seen the foul secretion from the throat of a patient about to die of scarlet fever produce sloughing of that portion of the integuments of another person with which it had remained for some time in contact, although the cuticle was stated to have been unabraded before the morbid secretion came in contact with it. The experiments of the French pathologists already referred to sufficiently prove the septic and disorganizing effects of putrid animal and vegetable matters when introduced into the healthy textures. It is supposed that, when a morbid secretion, or putrid animal secretion, occasions more or less of vascular injection of the part with which it comes in contact, or pain in connection with vascular injection or tumefaction, before disorganization ensues, this ultimate result is then the consequence merely of the morbid action more immediately preceding it, and that this action, more properly want of action, is inflammatory. But the truth is, that the septic agent, applied to the living part, deprived of its natural protection, or otherwise exposed, depresses the vital or the organic nervous endowment of that part, diminishes the tone of its capillaries, and weakens the vital cohesions of its tissues. As these changes proceed, the vessels are congested, the circulation through them is impeded, and ultimately ceases, and the part dies; although, in many instances, where the contaminating or poisonous agent is not sufficiently active thus to overpower or to annihilate the vitality of the part, and of the whole body, various attempts are made, by means of the vital resistance of the body, to oppose these changes, and to develop vascular reaction, whereby they may be the more successfully resisted. According to the intensity of the cause, relatively to the state of vital power and resistance, either of the part or of the body generally, or of both, will the effects, both local and general, thus vary; the more virulent or intensely contaminating or septic agents, destroying not only the part, but also the whole frame, and even hastening the physical dissolution of the body, without either vital resistance or vascular reaction being manifested, the less intense agents admitting of the development of both, in more or less efficient forms. In this latter case the septic tendency may be hardly apparent; and during the procession of morbid changes which the septic agent produces, congestion of, serous effusion into, and destruction of, the cellular tissue, and spreading inflammation and disorganization of the adjoining tissues are the most prominent organic lesions. My limits will not permit me to pursue the consideration of this

subject, which, however, is discussed at length under other heads, especially under CELLULAR TISSUE (§ 9, *et seq.*), DISEASE (§ 87, *et seq.*), ERYSIPELAS (§ 26, *et seq.*), INFECTION (§ 11, *et seq.*), and INFLAMMATION (§ 54, *et seq.*), while various specific maladies furnish illustrations, not only of the subject, but also of the principles for which I have contended, more particularly the HÆMAGASTRIC, AND THE SEPTIC OR GLANDULAR PESTILENCES, SCARLET FEVER, AND SMALLPOX. I therefore conclude with a brief notice of the effects produced by the poison of serpents, &c.

[In this connexion the reader will call to mind the remarks of LIEBIG relative to the modus operandi of poisons, which he illustrates by the fact that a body in the act of decomposition or change, added to a mixed fluid in which its constituents are contained, can reproduce itself in that fluid exactly in the same manner as new yeast is produced when yeast is added to liquids containing gluten. Thus, when blood, pus, gall, or cerebral substance is laid upon fresh wounds, vomiting, debility, and even death may be occasioned, as in dissection wounds, and poisoning by bad sausages, &c., the poisonous properties of which are destroyed by alcohol and boiling water.

There is certainly great plausibility in the doctrine that these substances communicate their own state of putrefaction to the same blood from which they were produced, exactly in the same way as gluten, in a state of decay or putrefaction, causes a similar transformation in a solution of sugar. So, also, poisons are generated by the body itself in particular diseases, as smallpox, plague, and syphilis, which have the property of reproducing themselves in like manner, or as seeds reproduce seeds. The peculiar power thus of animal poisons, at least, is probably owing to an active condition, recognizable by our senses, only through the phenomena which it produces.]

690. i. POISONOUS SERPENTS.—Many of this class of reptiles are more or less poisonous. The *viper*, or *Coluber berus*—*Vipera berus*—is the most common poisonous serpent in Europe; the *Cobra de Capello*, or *Coluber naja*, in the East Indies, and the several species of the *rattle-snake*, or *crotalus*, in America. But our information as to the genera and species of serpents or snakes which are actually poisonous is limited, notwithstanding what has been adduced by FONTANA, REDI, ATWELL, HORNER, ORFILA, and others. The bite of the *viper*, which is the only poisonous snake in Britain, seldom occasions death, although in other countries of Europe its poison is often much more virulent than in this; but the season of the year varies the intensity of the poison, which is greatest in summer and autumn.

691. A. The symptoms are acute or lancinating pain in the part wounded, commencing either instantly, or not for several minutes after the infliction of the injury, according to the intensity of the poison. The pain extends rapidly towards the trunk or centre of the body; and swelling, with redness or discoloration, passing to a livid hue, supervenes. These local changes are followed by faintness, or full syncope, bilious or convulsive vomitings, difficulty of breathing, copious cold sweats, dimness of vision; a small, quick, weak, and irregular pulse; yellowness of the skin; disturb-

ance of the mental faculties, and, in the most dangerous or fatal cases, the rapid progress of these symptoms and gangrene of the wounded part. Death may ensue, either rapidly or slowly; or recovery may take place, according to the virulence or activity of the poison relatively to the powers of the individual, or the aid and treatment he has received. Dr. WAGNER mentions two cases where the injury was on the toes, and death took place before assistance could be procured. In a case referred to by Dr. CHRISTISON, a burning pain was felt in the bitten foot, followed by intense pain in the belly, vomiting, incessant thirst, and death in three hours. Dr. BRAUN (*Rust's Magazine*, b. xxxii., p. 361) states, that a man who professed to be a snake-charmer, put the head of the *Coluber chersa* into his mouth, but suddenly threw the reptile from him, finding that he had been bitten near the root of the tongue. In a few minutes he became so faint that he could not stand. The tongue swelled a little, the eyes became dim, some saliva issued from his mouth, rattling respiration succeeded, and he died within fifty minutes after he was bitten. On the other hand, death may not take place until one, two, or even three days after the inoculation of the poison. The poison of the common viper is said not to be so dangerous in France as that of the *red viper*, which may cause death in a very few hours.

692. The activity of the poison of the viper, and indeed of all serpents, depends upon a variety of circumstances. When long confined, or after the animal has bitten frequently in rapid succession, and during cold seasons, when it loses its activity, the poison also loses its virulence more or less, owing either to a scantier, or a weaker, or an exhausted secretion. Serpents are most poisonous in warm, humid, and malarious climates, and are there most numerous. In those parts of Africa, which were chiefly of this description, that I visited, accidents from them were very frequent; but, owing to my residence at any place being short, I did not succeed in obtaining any of the poisonous species. The most dangerous bites are inflicted on naked or imperfectly-covered parts, particularly the extremities; and the more severe and virulent, the more rapidly are the symptoms developed. The poisonous properties of the fluid contained in the reservoir do not cease with the animal's life, but may continue, like some other poisonous fluids, as that of smallpox, &c., even when the fluid is dried and kept for some time. Professor MANGILI has demonstrated that it may be swallowed without injury. The *Fetish-men*, or native doctors in Africa, have in my presence, when sucking the wounds made by a poisonous serpent, swallowed the fluids thus drawn from the wound to show their powers and invulnerability.

693. The *Crotalus horridus*, or rattlesnake, produces effects which vary with the circumstances noticed above. Sir E. HOME states, that when the poison of this reptile is active, its local operation is so sudden and violent, and its effects upon the frame so great, that death soon takes place; and that, on examination after death, the only alteration of structure is in the parts close to the bite, where the cellular membrane is completely destroyed, "and the neighbouring muscles are very considerably

inflamed." But I can add, that the appearances of the muscles which are assumed as inflammatory are not actually such, but those of congestion and softening from loss of the vital and physical cohesion of the tissues.

694. When the poison is less virulent, the shock to the frame is rarely fatal. The pain in the part bitten is very severe, and in about half an hour swelling takes place from the effusion of serum into the cellular tissue, and continues to increase more or less rapidly for about ten or twelve hours, extending during that period to a greater distance from the wound. The blood afterward ceases to circulate in the smaller vessels of the swollen parts; the skin over them becomes quite cold; the action of the heart is so weak that the pulse is scarcely perceptible; a slight delirium is present, and the stomach is so irritable that nothing is retained on it. If the patient does not sink, these symptoms disappear in about sixty hours, and inflammation and suppuration take place in the injured parts, and when these are great the result is often fatal. The symptoms of those who recover go off more readily and completely than the symptoms produced by a morbid poison which has been received into the system. When the bite is in the fingers or toes, the part often immediately mortifies; and when death takes place in these cases, the absorbent vessels and glands present no change, nor has any part lost its natural appearance excepting those in the vicinity of the wound. The following cases illustrate the symptoms and morbid changes produced by this poison.

695. A person who took rattlesnakes from America to Europe for exhibition was bitten by one in Paris, and died in nine hours. On dissection, all the internal organs were found healthy, "excepting that the membranes covering the brain and spinal cord had a reddish tinge, and the venous blood on the affected side was curdled or clotted." (*Edin. Journ. of Science*, vii., 86.) Dr. HORNER states that a patient, whom he saw some hours after having been bitten in the arm by a rattlesnake, had the arm from the thorax to the fingers swollen to twice its natural size, and it was very painful when moved. The pulse was almost imperceptible; the extremities were cold; the eyes were muddy and heavy; the face bloated. Death took place twenty-four hours after the receipt of the injury, and five hours after death the body was examined. The face was then much bloated; the neck tumid and purple; the bitten arm was still swollen and purplish. The internal organs presented no lesion beyond congestion, which was most apparent in the vessels within the cranium and spinal canal. The cellular and adipose tissues of the injured arm were infiltrated with serum. The blood was fluid, and of a very dark colour. (*American Journ. of Med. Sciences*, vol. viii., p. 397.)

696. A man was bitten in London by a rattlesnake which was being exhibited. In less than half an hour the injured hand began to swell, and pain and swelling extended rapidly along the arm to the axilla. In two hours afterward the man's answers were incoherent, his skin cold, his pulse 100 in a minute, and he was sick at stomach. In eight hours the pain was extremely violent, the swelling very great, and he had frequent attacks of faintness.

The following morning his pulse was remarkably feeble, 132 in a minute, and slight swelling had extended from the arm along that side to the loins, with a mottled appearance from the exudation of blood under the skin. His whole arm was very cold and painful, presented several vesications, and "had a livid appearance, similar to what is met with in the dead body after putrefaction has commenced." On the third day his pulse was scarcely perceptible; the extremities were cold, and the vesications were larger. He rallied for a few days, but gangrene of the arm took place, and he died on the eighteenth day. Sir E. HOME, who records this case, adds, that Dr. RUSSELL communicated to him the details of a case of a man who had been bitten by the *Cobra di Capello*, and the symptoms were nearly the same as now stated. He also refers to two experiments he made on a couple of rats, which he caused to be bitten by a venomous serpent. The one first bitten died in one minute after the bite; and upon dissection, he found the cellular tissue under the skin of the side bitten entirely destroyed. The second rat was not so rapidly nor so severely affected, but it died in six hours.—(*Philosoph. Trans.*, 1810.)

[The *moscheto* and the *small black fly* deserve mention among insects whose bites are to some extent poisonous, and in a great degree annoying. A lotion of *vol. alkali*, properly diluted, is one of the best applications, and, as a preventive, smearing the parts exposed with camphorated volatile oil is generally pretty successful. We have found the bites of these insects so poisonous in the woods bordering on Lake Superior and our other northwestern lakes, as to cause such excessive inflammation and swelling of the skin as to obstruct the sight and cause general fever. Smoke, and every other means of defence, sometimes proved unavailable.\*]

[\* Dr. A. F. WAINWRIGHT of this city was recently bitten by a rattlesnake in the last phalanx of the middle finger of the left hand, near its articulation with the metacarpal bone, which was followed by a small jet of blood. The wound was immediately sucked, and in about half an hour after the bitten part was excised, and a ligature applied above the seat of injury. The limb, however, swelled rapidly, becoming mottled and œdematous. The tumefaction extended to the parietes of the chest, and he died in a state of collapse in five hours and a quarter after the receipt of the injury.

The particulars of the case, as detailed by Dr. A. C. POST (*N. Y. Annalist*, Feb. 1, 1848, p. 163), are as follows: From the nature of the parts involved in the wound, the incision must have been imperfect, but the excised surface was immediately cauterized. The ligature was tied firmly about the wrist, and ten grains *carbonate of ammonia* and half a grain of *sulphate of morphia* were administered; about seven and a half P.M., the ligature, after it had been on half an hour, was removed. Previous to this time the hand had been very much swollen, but no swelling had occurred above the ligature. It now began to extend up the arm. At nine and a half the patient was seen by Dr. P., when the swelling had extended to a point half way between the elbow and shoulder joint; it was very considerable, hard, and terminated abruptly; the finger, when passed along the arm, dropping suddenly from the swollen part to that in its natural condition. The hand was of a dark greenish colour; the lower part of the arm was mottled blue and greenish yellow; the discoloration did not extend as far as the swelling, and seemed to follow the swelling at about half an hour's interval. When first seen by Dr. P. the pulse was eighty, of medium fullness and strength, face flushed, and manner excited. Half an hour after the pulse began to flag, becoming less full and forcible, but increased to one hundred; it afterward reached one hundred and twenty beats in the minute, but became constantly more and more feeble. By eleven o'clock the pulse was extinct at the wrist, but could still be felt at the groin. Between ten and eleven he became stupid, taking

697. The *Coluber fulvus Australicus*, or "copper-coloured snake," has sometimes caused death or dangerous effects in Australia, where it and other allied species abound. In a case detailed by Mr. BLAND (*Lancet*, Jan., 1848), the bite nearly proved fatal, although ligatures were instantly placed upon the limb above the injury. The symptoms were pain in the region of the heart, with a feeling of constriction in the chest; acceleration of pulse; giddiness, jaetitation, dimness of sight, and general distress, which continued for some time, but were ultimately removed by the very judicious and active treatment adopted.

698. *B. Treatment.*—When the situation of the bite allows of the application of a ligature above it, then this practice should be instantly adopted; and even two ligatures ought to be applied, especially if a considerable time is likely to elapse before professional aid can be obtained. When the situation of the injury admits not of the application of a ligature above it, then a cupping-glass, or any vessel or eup which may be applied with sufficient exhaustion of the contained air to produce pressure around the bite, as well as to draw the fluids through it, should be resorted to and kept applied, or reapplied as efficiently as possible. When medical or surgical aid is obtained, *excision* of the bitten part, if the situation admit of its performance, should be adopted, especially if the symptoms are urgent and the local contamination manifest. But when these means cannot be resorted to, and even when they have been already employed, *suction* of the wound should be as instantly instituted as possible, and continued without intermission for a considerable time.\* The moderns have certainly not materially improved upon the treatment recommended by the ancients for the bites of serpents and other reptiles. If we refer to NIXON, DIOSCORIDES, CELSUS, and other Greek and Roman writers, as well as to the Arabians,

no notice of what was passing about him. This lapsed into complete coma, and he died a little past twelve. By this time the swelling had extended under the pectoral muscle, and the discoloration had reached the axilla.

The treatment consisted in the administration of stimulants, brandy and carbonate of ammonia, in as large doses as the patient could be prevailed on to swallow. When they could no longer be given by the mouth they were administered by the rectum, after the pulse had ceased at the wrist, and the surface covered with a cold perspiration. A sinapism applied to the epigastrium produced full redness in twenty-five minutes.

A fatal result from the bite of the rattlesnake is very rare in the United States, though bites are not infrequent. Dr. A. CLARK informs us that a man who kept these animals for exhibition stated that he had often been bitten, but that he possessed a remedy which always cured him. He was, however, at last bitten by a large one, and died in four hours. Cauterizing, with ammonia, immediately after animals, as cats and rabbits, are bitten, does not prevent a fatal result. In man the poison seems to attack especially the subcutaneous cellular tissue; the sloughing, when patients recover, being superficial. The phenomena bear no resemblance to those of ordinary inflammation, especially when death speedily results.]

[\* In nearly, if not all, cases of bite from a poisonous reptile, *suction* should be the first measure resorted to. In many cases it will alone suffice to ensure a safe result. Ligature, caustic, and excision are important adjuncts. The free use of alcohol alone, or mixed with oil of turpentine, has been found very successful in our Western States, where rattlesnakes are said to abound. Hunters not infrequently carry a bottle, containing equal parts of these articles, as a specific in case they are bitten. We know of no plant possessing specific curative virtues in such cases as claimed by the Indians, and believed by some writers. Of these pretended specifics, more than a score are already known and described in our books.]

we shall find them all recommending the means now advised, with several others. Mr. ADAMS, in his most valuable translation of PAULUS ÆGINETA, has given an excellent epitome of the treatment prescribed by the ancients for poisonous bites and wounds. They all recommend ligatures, cupping, suction, and, in urgent cases, excision or amputation. After sucking and cupping the wound, they advise stimulating dressings, and the application of the flesh of fowls, while still warm, to the part. They also recommend bleeding, "when the poison is distributed over the body," but at the same time they give wine and stimulants, emetics, and sudorifics, and agree in GALEN's eulogy upon the virtues of the theriaca. I must, however, refer the reader to Mr. ADAMS's work for a very full account of the practice of the ancients in these and in all other cases of poisoning.

698\*. In Mr. BLAND's case (§ 697), bleeding from the arm to the extent of sixteen ounces was adopted, "in conformity with his experience in these cases, and was followed almost immediately by the entire removal of both the pain and constriction." At ten the same evening the patient was again bled to ten ounces, some pain and constriction in the chest having returned. Besides the means already mentioned, Mr. BLAND advises "the exhibition of stimulants, as oil of turpentine, aromatic spirit of ammonia, brandy or other spirits, eau-de-luce, port, sherry, Champagne, or other wines." In addition to these, the head and face should be frequently sponged with cold fluids, as vinegar, rose-water, &c. I have seen, in Africa, where accidents from poisonous serpents are not infrequent, the juice of the citron, with capsicum, added to the other stimulants which were taken, and applied to the wound after suction had been continued for some time. The bowels were opened by means of olive oil, taken by the mouth with stimulants, or administered as enemata, with capsicum and salt. In the more intense states of poisoning by venomous snakes, bleeding can hardly be resorted to, owing to the extreme depression of the powers of life; and it is only when reaction is being developed by the aid of powerful stimulants that the loss of blood tends to relieve the vascular congestion produced by the poison, especially of the lungs and large vessels, and, by reducing the mass to the low amount of moving power, thereby to restore and equalize the circulation.

699. Various substances have been recommended as *antidotes* to the poison of serpents. HUMBOLDT and BONPLAND mention a New Granada plant, the *guaco*, *Mikiana guaco*, the juice of which is said to deter snakes from biting persons on whom it is applied; the leaves being also applied to the wound to prevent the usual effects when a person is bitten. (ORFILA, *Toxicologie*, t. ii., p. 441.) *Arsenite of potash*, and other preparations of arsenic, as the Pill of Tanjore, have been used in the East as an antidote to this poison. Dr. RUSSEL states that it was taken sometimes with success, but that it failed in other cases. Mr. IRELAND (*Trans. of Med. and Chirurg. Society*, vol. ii., p. 397) and Dr. PHILLIPS (*American Journ. of Med. Sciences*, vol. viii., p. 540) have furnished satisfactory evidence of the efficacy of arsenic, even in the worst cases of poisoning by the bites of serpents. Mr. IRELAND relates five cases in

which he prescribed the arsenic in very large doses. He states, that upon his arrival at St. Lucia, where venomous serpents are numerous, chiefly the *Coluber carinatus*, an officer and several men of the 68th regiment had died within a few months from bites of these reptiles; and notwithstanding the treatment, the patients had sunk in six to twelve hours from the time of their receiving the wound. The following case will show the symptoms and treatment of it and all the others.

700. A soldier was bitten in the hand, the middle finger being much lacerated, and it was immediately amputated at the joint with the metacarpal bone. He was seen ten minutes after he received the wound. He was then so torpid and senseless as to feel little or no pain during the operation. The hand, arm, and breast of the same side were much swollen, mottled, and of a dark purple and livid colour. He was vomiting, and appeared as if intoxicated. Pulse quick and hard. The wound being dressed, a cathartic clyster and the following were administered immediately: "℞. Liq. Arsenicalis, ℥ii.; Tinct. Opii, gtt. x.; Aquæ Menthæ pip., ℥iss." This medicine was added to half an ounce of lime juice, and taken immediately. It remained on his stomach, "and was repeated every half hour for four successive hours. In the mean time the parts were frequently fomented with common fomentation, and rubbed with a liniment composed of Ol. Terebinth., ℥ss.; Liq. Ammon., ℥ss.; and Olei Olivæ, ℥iss. The cathartic clyster was repeated twice, when the patient began to be purged; the arsenical medicine was now discontinued." From that time he gradually recovered. The next day he appeared very weak and fatigued; the swelling gradually diminished, and he soon recovered and returned to his duty.

701. The administration of large doses of ammonia and eau-du-luce has been advocated by many, and numerous instances of their success have been recorded, while HOME and ORFILA doubt their virtues. They are, however, useful in rallying the powers of life and in promoting perspiration. And in this way other stimulants, as alcoholic fluids in large doses, have also been of use. Many plants have likewise been much praised as antidotes to the bites of serpents, especially the *Aristolochia serpentaria*, the *Prenanthes alba* and *altissima*, the *Polygala senega*, the *Eupatorium ayaparia*, the *Ophioxylon serpentinum*, *Nux vomica*, &c.; but probably they possess no farther specific influence than in enabling, by their stimulating action, the vital powers to resist the injurious influence of the poison.

702. ii. VARIOUS INSECTS AND REPTILES, especially the *scorpion*, the *tarentula*, the *hornet*, the *spider*, the *wasp*, and the *bee*, produce serious effects in some constitutions by their stings. The effects of these, however, vary much. In some they resemble those produced by the bite of a viper; in others they are more slight, and are merely irritant locally, while they occasion more or less severe nervous symptoms.—A. The sting of the *scorpion* has, in some instances, produced severe diffusive local inflammation, with pain, fever, tremor, and depression. Dr. GRAFERN saw two cases in which the sting of the *tarentula* proved fatal in the Crimea—one in forty-eight hours, the other in six days. The sting, which was inflicted in the patient's neck,

was very painful, and had left a brownish violet mark. The neck, head, and shoulders were swollen; the thorax, from the clavicle to the false ribs, was of a bluish colour; and respiration became difficult forty-four hours after the injury. Searifications, the actual cautery, oil externally and internally, and ammonia, were all employed in vain. (*Quart. Journ. of For. Med.*, i., p. 215.)

703. B. Dr. Beck refers to a ease in which the sting of a *bee* caused vomiting, fainting, sweating, trembling, and great difficulty of breathing; and the sting of the *wasp* has caused similar effects, and sometimes even insensibility, with spasmodic twitches. Dr. Beck refers in a note to a statement that Dr. King, of Stratford-on-Avon, died on the 14th of June, 1833, in consequence of a sting which he received on the 8th of the same month from a *hornet*.

704. C. The treatment of the stings of these insects should be the same in principle as that advised for the bites of venomous reptiles; which is similar to that prescribed by the ancients, an epitome of which will be found in Mr. Adams's work, already referred to. In the less severe cases, emollient and anodyne applications to the wound are of use, after the sting is extracted; and the volatile alkali, or the other stimulants and restoratives mentioned above, should be given internally in large and repeated doses, when vital depression is alarming, or the other general symptoms are severe.

¶ In this article it will be seen that I have ventured upon a different CLASSIFICATION of poisons than has hitherto been proposed; and that I have based this classification upon what I believe to be the operation of such substances as have been found to be more or less injurious to the living human body. It may be some reason for this arrangement, that there is scarcely a poison which is not, or has not been, employed as a medicine, and therefore some reference should be had, in our consideration of the *modus operandi* of poisons, to the nature and effect of these substances when employed medicinally; and, in fact, it is upon what is known, and upon what I believe, to be the influence and action of these substances that I have founded my arrangement. I offer it to the examination of the closely observing and profound pathologist, therapist, and medical jurist; and to several such I have been much indebted in the preceding pages. There are numerous substances, both medicinal and poisonous, which are arranged with great difficulty according to their operation and more prominent effects, owing to the circumstance of their operation taking place through different media and channels; and to the fact that the effects upon the different vital organs vary in different persons, from causes already stated, and even in the same person at different times, seasons, and states of the digestive organs, and of the economy. Hence substances which may appear to some to belong to a certain class, may seem, with equal justice to others, to belong to a different class. But this objection is one to which all arrangements are liable, where the objects to be arranged present not sufficiently distinctive characters on which specific differences may be based. There may be some imperfections in my views, and I may have to modify certain of them, especially as respects those substances the nature of which has been insufficiently investigated; but I have endeavoured to be as precise and correct as the extensive range of the subject and my limited powers allowed me to be; and I have endeavoured to do justice to all who have furnished me with information in their able and classical productions.

The reasons for my excluding chemical and juridical disquisitions from my treatise have already been given; but I may again state that they are not comprised by the scope of my work, or by its limits; and I am desirous that they should be referred to in the practical and able sources which I have already indicated. My object—and, indeed, my duty—was to describe the operation, the effects, the diagnosis, and the treatment of poisons, as a most important part of Practical Medicine—as, in truth, states of disease, although produced by art, or with the intention of destroying life—as no mean or small part of medical practice and usefulness—and as contributing in no small degree to the medical practitioner's knowledge, not only of the sources and course of the most intense and rapid states of morbid action and of

their results, but also of the operation and effects of our chief medicinal agents in alleviating and in removing spontaneous or natural maladies.

In order to facilitate reference to the PRINCIPAL TOPICS and to the INDIVIDUAL SUBSTANCES comprised in the article POISONS, I add the following synopsis, with the number of the paragraph at which the consideration of them commences.

- I. THE MODES IN WHICH POISONS ARE ADMINISTERED, &c., § 2.
- II. THE ACTION OF POISONS CONSIDERED, § 11.
- III. THE MEDIA OR CHANNELS BY WHICH POISONS ACT, § 18.
- IV. THE GENERAL EFFECTS OF POISONS, § 28.
- V. THE SPECIAL OPERATION OF POISONS, § 34.
- VI. THE CIRCUMSTANCES WHICH MODIFY THE EFFECTS OF POISONS, § 51.
- VII. A GENERAL VIEW OF THE SYMPTOMS OF POISONING, § 67.
- VIII. THE GENERAL DIAGNOSIS OF POISONING, § 73.
- IX. OF THE DIAGNOSIS OF POISONING DURING DISEASE, § 91.
- X. THE GENERAL PRINCIPLES OF TREATMENT IN CASES OF POISONING, § 98.
- XI. CLASSIFICATION OF POISONS, § 106.
- XII. OF THE SPECIAL EFFECTS AND TREATMENT OF POISONS, § 108.

#### CLASS I. ACRID AND CORROSIVE POISONS, § 109.

- i. Symptoms and Diagnosis of corrosive poisoning, § 109.
- ii. Acids.—A. Acetic acid, concentrated, § 125.  
B. The mineral acids, the hydrochloric, the nitric and sulphuric acids, § 132.  
C. Oxalic acid, § 159.
- iii. Alkalies and their carbonates, § 167.
- iv. Antimony, chloride of, § 175.
- v. Iodine and bromine, § 179.
- vi. Lime, unslacked, § 189.
- vii. Phosphorus, § 192.
- viii. Salts.—Alkaline corrosive, § 196.  
A. Bichromate of potash, § 197.  
B. Binoxalate of potash, § 198.
- ix. Salts—Metallic corrosive, § 199.  
A. Of Antimony, § 200.  
B. Bismuth, trisnitrate of, § 201.  
C. Copper, preparations of, § 205.  
D. Gold, chloride and iodide of, § 211.  
E. Mercury, bi-chloride of, § 216.  
Nitrates, bi-cyanide, and some other preparations of, § 226.

F. Silver, nitrate of, § 229.

G. Tin, the chlorides of, § 231.

H. Zinc, chloride and sulphate of, § 232.

#### x. Vegetable acids, § 234.

- a. Anemone, the poisonous species of, § 235.
- b. Arum maculatum and A. dracunculus, § 236.
- c. Brionia dioica, § 237.
- d. Caltha palustris, § 238.
- e. Chelidonium majus, and other species, § 239.
- f. Croton tiglium, § 240.
- g. Cucumis colocynthis, § 242.
- h. Cyclamen Europeum, § 244.
- i. Daphne gnidium and D. mezereum, § 245.
- k. Delphinium staphysagria, § 246.
- l. Euphorbia officinarum, and other species, § 247.
- m. Gratiola officinalis, § 249.
- n. Hippomane mancinella, § 250.
- o. Iotropa curcas, § 251.
- p. Juniperus Sabina, § 252.
- q. Monardica elaterium, § 253.
- r. Narcissus pseudo-narcissus, § 254.
- s. Ranunculus, several species of, § 255.
- t. Rhus toxicodendron, § 256.
- u. Stalagmitis cambogioides, § 257.
- v. Other acrid and corrosive plants, § 258.

#### CLASS II. DEPRESSING AND PARALYZING POISONS—SEDATIVE POISONS, § 261.

- A. Acetic acid, in frequent doses, and diluted, § 262.
- B. Acids, the mineral, frequent doses of the dilute, § 263.
- C. Alkalies and their carbonates, prolonged use of, § 264.
- D. Cold or abstraction of animal heat, § 265.
- E. Digitalis purpurea, § 266.
- F. Lead, preparations of, § 275.
- G. Prussic or hydrocyanic acid, and its compounds, § 289.
- H. Zinc, oxide of, § 321.
- I. Vapours of ether and alcohol, § 322.

#### CLASS III. EXCITANTS—STIMULANTS—EXCITING AND EXHAUSTING POISONS, § 323.

- i. Alcohol, § 324.
- ii. Ethers, § 336.
- iii. Camphor, § 341.
- iv. Chelidonium majus and C. glaucium, § 352.
- v. Heat, in various forms, § 353.

vi. *Ipecacuanha*, § 358.

CLASS IV. EXCITING AND CONSTRICTING POISONS—NERVOUS AND MUSCULAR EXCITANTS, § 361.

i. *Alum*, § 363.

ii. *Nux vomica* and *Strychnia*, § 364.

Various plants containing *Strychnia*, § 370.

iii. *Bacca antidyssenterica*, &c., § 378.

iv. *Cocculus Indicus*, § 379.

v. *Conaria Myrtifolia*, § 381.

CLASS V. IRRITATING AND DEPRESSING POISONS—IRRITATING AND PARALYZING POISONS—ACRO-SEDATIVES, § 382.

i. *Aconite*: varieties of *A. napellus*, § 383

ii. *Arsenic* and its compounds, § 393.

iii. *Colchicum autumnale*, § 419.

iv. *Hellebore* and its species, § 423

v. Food poisons, § 427.

A. Poisonous fish, § 428.

B. Poisonous meats, § 434.

C. Diseased animal substances, fluids, secretions, &c., § 444.

vi. Mineral and saline acro-sedatives, § 451.

A. The antimonial compounds—*Tartar emetic*, &c., § 452.

B. *Baryta* and its salts, § 458.

C. Cupreous preparations and compounds, § 464.

D. Salts of potash, § 475.

E. Sulphurets, § 481.

F. *Tartaric acid*, § 485.

vii. The necroscopic poison—Poison imbibed from recently dead bodies, § 487.

viii. Putrid animal matters, § 519.

ix. Tobacco—Indian and Virginian, § 523.

A. Tobacco smoking, § 527.

B. Tobacco chewing, § 528.

x. Other vegetable acro-sedatives, § 534.

A. Castor seeds, § 534.

B. *Atropa* *manihot*, § 535.

CLASS VI. IRRITANT AND ALTERANT POISONS—ACRO-ALTERANT POISONS, § 536.

i. *Belladonna*, § 537.

ii. *Cantharides*, § 546.

iii. Chlorine and the chlorides, § 553.

A. Chlorine gas, § 553.

B. Chlorate of potash, § 556.

C. The chlorides and the hypo-chlorides, § 557.

iv. Iodine and its compounds, § 558.

v. Mercury, the preparations of, § 562

A. Mercurial vapours, § 564.

B. Mercurial salivations, &c., § 568.

C. Mercurial diseases, § 570.

vi. Thorn-apple, § 592.

CLASS VII. NARCOTICS OR STUPEFYING POISONS—HYPNOTICS, § 598.

i. Carbonic acid gas, § 600.

ii. Carbonic oxide gas, § 610.

iii. Carburetted hydrogen gas—Coal gas, &c., § 611.

iv. Chloroform and the ethers, § 615.

v. *Cicuta virgata*—Water-hemlock, § 617.

vi. *Conium*—Hemlock, § 619.

vii. *Henbane*—*Hyoscyamus*, § 624.

viii. *Opium*, and its preparations, § 630

a. *Opium* eating, § 637.

b. *Opium* smoking, § 641.

c. *Morphia* and its salts, § 650.

ix. Sulphuretted hydrogen gas, § 661.

CLASS VIII. NARCOTIC AND IRRITANT POISONS—ACRO-NARCOTICS—NARCOTICO-ACRID POISONS, § 667.

i. *Empyematic* oils, § 668.

ii. *Fool's-parsley*, § 689.

iii. *Fungi*—Poisonous mushrooms, § 670.

iv. *Hemlock* dropwort, § 680.

v. Grain, diseased, § 681.

vi. *Laburnum*, § 683.

vii. Leguminous seeds, § 684.

viii. *Lolium Temulentum*, § 685.

ix. *Yew-tree*, § 686.

CLASS IX. SEPTIC AND DISORGANIZING POISONS, § 687.

i. Remarks on various septic poisons, § 688.

ii. The bites of various poisonous serpents, § 690.

iii. The stings of insects, &c., § 702.

1. **DEFIN.**—*Voluntary and solitary excitement of the sexual organs, occasioning emissions or the venereal orgasm* (self-pollution—voluntary pollution). *Discharge of the seminal fluid, with or without the venereal orgasm, involuntarily or during sleep* (involuntary pollutions).

2. Under the designations, *voluntary and involuntary pollutions*, I propose briefly to consider those moral and physical disorders which have been variously denominated according to the forms in which they have been presented to the medical adviser, or which they have assumed in the progress of moral depravity; not infrequently in connection with outward moral observances and hypocritical sanctity. That form of pollution, in either sex, which was at first voluntary, generally becomes involuntary when the evil habit is persisted in, although the latter, in certain circumstances, may occur primarily. It becomes, therefore, necessary to consider the different states of this important disorder in succession, inasmuch as the moral vice is generally the cause of the physical disease. Both states of the disorder should be viewed with a due regard to their special relations and consequences; for so remarkably important are these consequences—so numerous are the ills, both of body and mind, which this disorder induces—and so certainly are those ills entailed upon the subsequent life of the person who is its subject, and upon his offspring to the third and fourth generation, if, indeed, he possess the power of propagating his species, even in the most imbecile forms, that it becomes the duty of the medical instructor to point out its forms, relations, and consequences. The subject has been improperly neglected by both instructed writers and scientific physicians, because it is one frequently involving delicate ideas, and requiring unpleasant revelations—as the due consideration of it unveils the innate and concealed depravity of our nature. But the vice, the moral depravity, of which the disorder at first consists, soon creates for itself, in actual and often incurable physical disease, a necessity for disclosure—a necessity which is not confined to the person concerned, but extended to his family and his

offspring. This being the case with disorders and their usual consequences, which involve so extensive and important considerations, should they be relinquished by the only persons who are able to investigate them aright, and to restore the mental and the physical imperfections upon which they depend, and be handed over to ignorant harpies, who prey upon the wretched sufferers, who take the utmost advantage of the fears which torment them, of the moral and physical debility which sinks them, and of the circumstances in which they are involved, to deceive, to plunder, and to swindle them, and who have neither the knowledge, nor the ability, nor even the intention, to render them any aid!

**I. SELF-POLLUTION—VOLUNTARY POLLUTION.**—**SYN.** *Masturbation*—*Manustupration*—*Onanism*, &c.

**CLASSIF.**—GENERAL PATHOLOGY—*Ætiology*—*Pathogeny*.

**SPECIAL PATHOLOGY.**

**I. CLASS. II. ORDER** (*Author*).

3. i. **OCCASIONS, CAUSES, &c.**—I have already noticed, in a few sentences, the consequences of the too early and inordinate excitement of the genital organs in both sexes (*see art. Disease*, § 53); but the real importance of the subject induced me to mention merely certain prominent matters, and to reserve the fuller consideration of it to a more appropriate place. Self-pollution is generally a vice of *puberty*, but it frequently is often practiced at the earliest appearance of this epoch; and in females even long before the usual accession of this change. In both sexes, the habit is not infrequently continued through a considerable portion of after life. Several writers whose works I have perused have stated that they have known instances where this vice had commenced in females as early as three or four years of age; and cases of it have come before me when this age was hardly passed. At this early age, the practice has generally been acquired from the girls to whom the care of children has been committed. In a case of nymphomania, in a patient to whom I was called in consultation, and who was sixteen years of age, the intelligent mother, the wife of an eminent physician in India, stated that the disease originated in manustupration acquired from a native Indian nurse, when the child was only four years old. It is difficult to determine how early in life this vice may commence in the *male sex*. A patient who lately consulted me respecting his presumed impotence, stated that he commenced this vicious practice as early as eleven years of age; and I find, upon referring to my African memoranda, that it is common among negro boys of nine and ten years of age. But in this country, from thirteen years of age to twenty-five, and even upward, is the period in which it is commonly indulged, although its evil consequences are often found out before or soon after this latter age. At whatever period commenced, the habit is carefully concealed from parents and others; and is often not detected, nor even suspected, although both mind and body are reduced by it to the lowest state of imbecility.

4. It is requisite to be aware of the early age at which this vice may commence, as well as of the *circumstances* in which it commonly origi-

nates. One chief occasion of its early appearance has already been noticed; and this should suggest precautions, especially as respects the persons with whom children are allowed to sleep or to associate. Boarding-schools and other seminaries or institutions, where a number of children or young persons are brought together, and especially where several sleep in the same apartment, or more than one in the same bed, are the places where this vice is most frequently acquired, by both sexes; but it is not infrequently practiced by those who have never entered these places, it being either suggested by the local irritation and physical excitement often present during early puberty, or soon after this epoch, or acquired from tutors and governesses. The neglect of *circumcision* in Christian countries is certainly no mean physical cause of the prevalence of this vice, and of many of the consequences which follow. The institution of this rite for the descendants of Abraham, and the faithful observance of it to the present day not only by them, but also by the followers of Mohammed, have tended, amid numerous countervailing influences and persecutions, to perpetuate an enduring and healthy race; the beneficial results of circumcision being experienced not only by the individual himself, but also by his offspring, and even indirectly by the female sex, as may be inferred from various physiological considerations.

5. Although this vice is most prevalent among young persons, its ill effects generally becoming apparent to them with riper years, yet it is not infrequently indulged in, by persons of both sexes, during advancing years; and is generally the cause of most of the complaints observed in unmarried persons after the age of twenty-five years, as well as sometimes before that period. It is certainly the chief cause of the lives of this class of persons being of much less mean duration than those of the married.

6. There are few causes of this disorder more influential than idleness—than the want of such occupations for youth as require early rising. A full and active occupation of the mind generally shuts out all ideas which suggest this mischief, while the pleasures in which idleness favours the indulgence tend to encourage those ideas. Lying in bed after being awake is another occasion of no small importance—of much greater than is generally attached to it. Although this and several others of the foregoing causes may not have first occasioned this vice, still they remarkably favour a frequent recurrence to it, and often render the morbid impulse to it too strong for the self-control of the person who has fallen into the habit.

7. ii. THE SYMPTOMS AND SIGNS OF Masturbation are in some cases obvious almost on the first glance; in others, they require close observation, aided by experience of the several phases they assume. When the mischief has not been long indulged in, then the injury sustained by the organization is seldom such as to be manifest. But when it is commenced at an early period of puberty, or with the first indications of puberty, then its injurious effects show themselves much sooner than when the frame has previously been fully developed; and are much greater, especially at this early age, than the due congress of the opposite sexes. That

the injury done to the constitution by this vice is always much greater than that caused by sexual intercourse is certainly the case, although the act may not be oftener repeated in the former than in the natural way. As respects the female sex, this result may be easily accounted for; but it also obtains, and may be explained, as respects the male sex; for, independently of its being an act opposed to the dictates of nature and religion, it is one which exhausts the nervous powers more completely than the orgasm consequent upon reciprocal enjoyment, and the interchange of nervous emanations. But it should be recollected that self-pollution is often commenced at an earlier or more immature age than that at which the intercourse of the sexes can take place in the usual states of civilized society; and that hence it is the more injurious, because it impairs or interrupts the due development of both mind and body, at a period when such development receives, in the healthy frame, its chief impetus and full consummation from the genital organs and secretions. There can be no doubt, however, that the individual who has once devoted himself to this Moloch of the species becomes but too frequently its slave to an almost incredible degree. A patient who was sent to London for my advice confessed that he had practiced this vice seven or eight times daily from the age of thirteen until twenty-four; and he was then reduced to the lowest state of mental weakness, associated with various bodily infirmities; indeed, both mental power and physical existence were nearly extinguished.

8. a. The more prominent symptoms of self-pollution are readily recognized; but those which indicate an early stage of the habit are less manifest. In females, who often commence it long before, or with the earliest appearance of puberty, it is indicated chiefly by pallor or loss of colour, a desire to be alone, a somewhat dejected manner, listlessness and indolence, a desire to go soon to bed, and to lie long after having been awake; a darker mark than usual under the eyes, or of the lower eyelids; a near or weak sight; slight emaciation, although the appetite is good or even ravenous; the habit of biting the nails, which are generally very short; warts on the first or second fingers, slight sores about the roots of the nails, &c., are signs often observed; and when several of them exist in the same case, suspicion of self-pollution may be entertained; and may be viewed as confirmed, if slight leucorrhœa, with redness and considerable development of the clitoris and nymphæ be present, and especially if the linen or sheets betray any marks or stains. Several of these symptoms may be observed in males; but the night-linens most commonly demonstrate this vice in them. They, however, often prevent it from being thus detected, and completely conceal it until their appearance sufficiently betrays them.

9. When self-pollution is not frequently practiced, it may be very long before it is detected—if detected at all; but when it is a frequent habit, the above symptoms then are not of long duration without being followed by others, which more decidedly indicate the mischief. The signs, however, vary with the age. When early practiced, or before the frame is developed, or while the frame is in course of devel-

opment, this process is more or less impaired, or even interrupted. The organic nervous influence and vital power are determined chiefly to the immature sexual organs, and all the other vital manifestations languish more or less. The functions of digestion and assimilation are weakened, the blood is poor and deficient in red globules and hæmotosin, and a state of anæmia is more or less completely produced. The muscles become flaccid, and the tendons, ligaments, and capsules relaxed and easily stretched. The nervous systems are weak, susceptible, readily excited or depressed, and ultimately betray farther disorder. Hence arise weakness of the joints, flexures of the spinal column, chlorosis, chorea, epilepsy, rheumatic or neuralgic pains, nervous headaches, and a general blight of the constitution, often associated with worms in the intestinal canal, and always attended by mental and bodily indolence, chilliness, and susceptibility of cold, and by incapability of intellectual and physical occupation. At this early age, or when puberty is either not commenced or is just appearing, the patient is often stunted in growth by this habit, or is rendered decrepit and imbecile, the ovaria and the testes are imperfectly developed, and even waste more or less, and the beard in males hardly appears. I was first consulted by the parents of a young lady when she was about twelve years of age. She was then suffering from debility and slight anæmia; and subsequently she was the subject of chlorosis and tubercular consumption, of which she died about the age of twenty. She had never menstruated. When the body was examined after death, the ovaria were remarkably small, and changed to a dense fibro-cartilaginous state. It was ascertained during my attendance that she had become early addicted to masturbation; she ceased to grow at an early age, and was of a small and weak conformation, although her parents were large and strong persons. Most of those who thus early become addicted to self-pollution are soon afterward the subjects, not merely of one or more of the ailments already noticed, but also of enlargements of the lymphatic and other glands, ultimately of tubercular deposits in the lungs and other viscera, or of scrofulous disease of the vertebrae or bones, or of other structures, more especially of the joints.

10. *b.* When self-pollution is commenced at a more mature age, or when puberty is advanced or completed, the mischief which the constitution sustains is not so remarkable, nor so rapid in its progress as when practiced earlier; for the frame is then farther developed and more consolidated, and the powers of life furnish a greater resistance to the evil. Nevertheless, the consequences are generally most serious, especially when the vice is often indulged in; and, in some respects, are similar to those already mentioned, while those most frequently observed at this more mature age are not unfrequently seen also in younger persons. Stooping and roundness of the shoulders, with a falling inward of the thorax below the clavicles; emaciation and weakness of the joints; pallor of the countenance, with sunk orbits, the eyes being surrounded by a darker circle; a weak or dim sight, or nearness of the sight, weakness and pains in the eyes often preceding the

change in the focus of distinct vision; eruptions on the face; a falling out of the hair, and baldness of the crown and forehead; pains in the head, lowness of spirits, and aching of the back and loins, with inability of sustaining long an erect or even a sitting posture without support; marked aversion from leaving bed in the morning, and indisposition to enter upon any mental or bodily occupation, are the earliest indications of self-pollution at the more mature periods of life. To these succeed, sooner or later, loss of colour, a pallid state of the gums, tongue, and prolabia; sometimes a dusky hue of the countenance, with sores of the face, which are frequently picked and irritated by the patient; leucorrhœa, and delayed, or suppressed, or interrupted, or painful and difficult, or scanty menstruation; in some females, protracted or frequently-recurring catamenia; numerous hysterical symptoms, often irregular or anomalous, and attended by painful, or spasmodic, or slightly paralytic symptoms, and with all the phenomena noticed when treating of HYSTERIA and SPINAL IRRITATION. Ultimately, all the bodily functions betray increasing disorder, and special forms of disease succeed, particularly epilepsy, glandular and tubercular maladies, phthisis; palpitations of the heart from the slightest mental and physical causes, often protracted and excessive, and not unfrequently followed by organic changes of the parietes of the cavities, or of the orifices and valves of the heart; morbid states of the urinary functions and passages; hypochondriasis, and a morbid concentration of the attention upon the various changes and states of sensibility or of disorder, thereby aggravating these forms; melancholia, attended by various delusions, by unfounded fears, and a state of mental misery; and, at last, complete prostration of the powers of both mind and body, in various forms of partial or general insanity, or of incomplete or complete palsy; this latter affection often commencing as partial paraplegia, and advancing to incomplete general palsy of motion, the movements resembling those of chorea, and ultimately terminating in complete general palsy, with marked disorder of the urinary secretion and excretion.

11. *c.* During the progress of the ills which self-pollution entails, the digestive and the assimilating functions suffer more or less; the amount of disorder which these betray varying with the advantages enjoyed as respects food, air, exercise, and sleeping arrangements. But, generally, these functions and nutrition languish remarkably, and the bowels become habitually, sometimes obstinately, costive. Among the most certain signs of self-pollution, especially in males, is premature baldness; but it should be admitted that it not unfrequently is also produced by low fevers as well as by venereal excesses. Abuses of the sexual organs are soon followed, not only by one or more of the maladies enumerated and by constitutional exhaustion, but also by more or less disorder and debility of these organs themselves, frequently amounting to temporary impotence and sterility. The frequent and unnatural excitement of these organs occasions an increased secretion of the prostatic fluid, and often, also, acute or chronic inflammation and enlargement of the prostate gland, and all the usual consequences; increased susceptibility and impaired

or exhausted function of the virile organs; irritation of the seminal passages, and ultimately involuntary emissions, and wasting of the testes.

12. *d.* The mischief is seldom so rapidly manifested in the female as in the male, unless the practice commence before the full evolution of puberty. After this period, however, the evils which result depend much upon the frequency of the habit; but these vary accordingly, the state of the constitution, temperament, and predisposition, also, modifying the effects. These effects have already been enumerated; but they either cause, or are connected with sterility, which is generally owing to the changes produced in the ovaria by excessive, frequent, and unnatural excitement, and sometimes, also, in the uterus and Fallopian tubes. Independently of changes in the ovaria and tubes, and often antecedent to these, leucorrhœa is frequently present, and is sometimes followed by ulcerations of the os uteri, and numerous sympathetic ills which this state, in connexion with irritation of the ovaria and uterus, generally entails. The occurrence of ulceration, and the aggravation of it, are remarkably favoured by the means too frequently and officiously resorted to in ascertaining the nature of the uterine disorder; for by these means the access of air to the seat of irritation oftener increases the mischief than the remedies prescribed tend to allay it.

13. *c.* The *evil consequences* of self-pollution are, however, not confined to the individual; but, as already stated, *are transmitted to the offspring*, when the effects have not been such, as to kind and degree, as to prevent procreation. But when the constitutional powers, and more especially the sexual organs, of either sex are much weakened by this vice, either sterility is the consequence, or the offspring is delicate, puny, decrepit, or the subject of various congenital maladies, especially of the nervous system: to idiocy from deficient development of the brain, to hydrocephalus, to epilepsy, convulsions, palsy. The scrofulous diathesis, tubercular and glandular maladies, diseases of the vertebræ and of the joints, hydrocephalus, softening of the central portions of the brain, and tubercular formations in the membranes, palsy and convulsions, chorea, inflammations of the membranes or substance of the brain or of the spinal cord, and numerous other affections to which delicate infants and children are liable, very commonly result from self-pollution having been practiced by either of the parents previously to the married state. But the evil does not always stop at this epoch of existence; it often extends throughout the life of the offspring; or it appears only with puberty and mature age. The several diseases actually proceeding from tubercular deposits; insanity, or mental weakness, or imbecility; pulmonary consumption, chronic debility, or faulty or impaired development of the frame; diseases of the spine and joints; hysterical and neuralgic affections, epilepsy, and irregular forms of convulsion, partial or complete states of palsy, and various other affections not unfrequently appear, in consequence of the constitutional predisposition arising from the vice of the parent, and the faulty development and impaired nervous energy of the offspring.

II. INVOLUNTARY POLLUTIONS.—SYNON. *Invol-*

*untary discharges of spermatic fluid.—Spermatorrhœa.—Involuntary seminal discharges.*

14. *A.* This form of pollution is of very frequent occurrence, and generally follows the foregoing. When self-pollution has been practiced at an early age, or so frequently as to induce debility, or an irritable state of the sexual organs, involuntary discharges of spermatic fluid are often—indeed generally—the consequences of the relinquishment, or even of a temporary cessation of the voluntary acts. It has been believed, since the appearance of M. LALLENAND's work on this disease, and of Mr. B. PHILLIPS's excellent papers on the same subject, that these discharges “are for the most part, if not altogether, caused by irritation set up in or about the ducts connected with the testicle,” especially at the termination of the seminal ducts in the urethra. Such is, doubtless, the case in many instances; but it is much more generally only a part of the mischief; the whole genital apparatus, more particularly the seminal ducts and vesicles, the ejaculator muscles, and the prostate gland having acquired, from the *vicious practice* above exposed, an irritability and susceptibility beyond the control of the individual. *This practice is the chief cause* of this morbid condition—of this often serious disease, which, if not corrected, generally induces other maladies, although, when it is only of occasional occurrence in robust persons, it is sometimes productive of little injury. Yet self-pollution is not the only cause. The next to it in importance are excesses in sexual intercourse, the constant excitement of the sexual organs ending in a morbid susceptibility, debility, and irritability of the whole sexual apparatus, manifested especially by the parts just named. Gonorrhœa, gleets, discharges, and strictures of the urethra are also, although much more rarely, concerned in the production of this disorder. The irritation of ascarides in the rectum, of hæmorrhoids, of fissures of the anus, &c., has also been considered as one of the causes of these discharges; but I suspect that these morbid states are more frequently associated effects of the same causes—of masturbation and sexual excesses—than the actual occasion of the seminal emissions, even in those cases in which they coexist. However, whether the irritation of the rectum be a cause or a complication of the disorder now being considered, is practically of the less importance, that in either case it equally requires to be removed by suitable treatment.

15. *B.* The *evidence of involuntary spermatic discharges* is, as Mr. PHILLIPS correctly remarks, sufficiently clear; but ultimately, and as the weakness of the organs increases, the ejaculation is unattended by the usual sensations, and the patient may then be unaware of the extent of the evil. It is not unusual, in such far-advanced cases, to find the spermatic fluid passed with the urine, or during efforts at stool, especially when the bowels are costive. In the latter circumstances, the fluid is squeezed out by the pressure on the seminal vesicles. The patient is, however, generally aware of the evil when the fluid is passed with the urine, because it almost always passes with the last drops, and can then be detected, and is attended by a certain sensation about the neck of the bladder. When the urine is examined soon after

it is passed, small granular diaphanous particles are found floating in it, or at the bottom of the vessel. Mr. PHILLIPS states, that when the evil is far advanced, no peculiar sensation is experienced, and the granular matter may be undetected, or may assume a more uniform cloudy appearance. The microscope most certainly detects the seminal fluid in the urine, for by its means the spermatic animalcules may be perceived in the deposite or cloudy portion of the urine. As debility of the constitution or of the sexual organs increases, owing to the great frequency of the discharges, or to other causes, "the fluid becomes thinner, and the animalcules much less numerous, and they may be almost, if not altogether, wanting."

16. *C. The general symptoms or consequences of involuntary pollutions are necessarily, in most respects, the same as I have above stated with reference to self-pollution; for as the involuntary is generally caused by, or is a sequela of, the voluntary discharges, the results, as respect both mind and body, will generally be the same.* One of the most distressing of these to the mind of the patient, is a state approaching, if not actually amounting to, impotency. In some cases, the impotency is owing more to the fears and anxieties of the sufferer than to the physical state of the organs. Mr. PHILLIPS has described this complaint so well, that I shall adopt nearly his own words. It is not that the seminal fluid is deteriorated, or incapable of determining fecundation, but it is that the organs are wanting in the energy necessary for projecting the fluid into the vagina; erection, if it exists at all, being momentary. The digestive functions become deranged, the bowels constipated, nutrition languishes, respiration is troubled, the voice fails, the heart's action is interfered with, even to such an extent as to induce helief of actual disease of that organ, and hypochondriasis becomes complete. These symptoms do not advance far without causing disorder of the nervous system, especially weakness, or failure of one or more of the senses; headache, with a sense of weight or pressure, loss of memory, timidity, apprehension, and various other affections and diseases, either similar to, or identical with, those already mentioned (§ 9, *et seq.*).

17. But the impotency which distresses the patient is not so often imaginary as it is real. The frequent seminal emissions are followed by a thinner and less fully elaborated secretion with a morbidly increased prostatic fluid; and the imperfect and momentary erections, and the rapid emissions, are insufficient to excite the female orgasm requisite to procreation in most cases, or at least to a healthy impregnation and offspring. The impotency, however, is not the only evil; for it soon becomes associated with others if the seminal discharges continue, most generally with epileptic or convulsive affections, with palsy, with pulmonary consumption, with mental delusions, or general insanity, with distaste of life, and thoughts of, or attempts at suicide, or with some other of the various maladies which I have already shown to follow frequent self-pollutions (§ 9, *et seq.*).

18. III. TREATMENT.—i. *Of Self-pollution.*—It is obvious that treatment must necessarily fail, or at best only lessen the ill consequences,

as long as this vice continues to be practiced. It should, however, be recollected that it is not only most necessary that this vice, in all its moral and physical consequences, ought to be exposed to the patient, and the entire relinquishment of it insisted upon, but that those who have, or ought to have, control over him or her should ascertain whether or not the prohibition be strictly observed; for the control of reason generally becomes so weak in these persons as to be quite insufficient to restrain those impulses which the occasions mentioned above (§4-6) too frequently favour or excite. It should not be overlooked that physical conditions and local irritations are often the causes of many of our most uncontrollable desires and passions; and that professional inquiries ought to be directed to the state of those organs which not only are influenced by these desires, but which instinctively excite the desires themselves, independently of reason and volition. There can be no doubt, as I have above stated (§ 4), that the occurrence of this vice is remarkably favored by the physical condition of the male genitals, especially as regards the neglect of circumcision. I am convinced that the abrogation of this rite among Christians has been injurious to them, in religious, in moral, in physical, and in sanitary and constitutional points of view; that circumcision is a most salutary rite, as respects not only the individual, but also the female whom he marries, and his offspring. He who devotes himself to self-pollution—to this modern Moloch of the species—should duly consider the severe denunciations and punishments which it provoked from the Jewish legislator, and observe its enervating effects upon himself, both mentally and bodily.

19. It is necessary, not only to procure a complete relinquishment of this vice, but also to restore the several functions—sexual, digestive and assimilative, nervous and mental—to their healthy conditions. As the manifestations of these several functions are more or less debilitated by this vice, the advice which I have given at full length in the article DEBILITY (§ 29, *et seq.*) should be adopted and strictly followed in all its various details. Tonics, suited to the peculiarities of the case, ought to be prescribed, especially the chalybeate tonics, and mineral waters; and these should be aided by residence in a healthy air, by regular exercise, by full occupation, and by early rising. The patient should get out of bed instantly upon awaking in the morning, and have recourse, either to a shower-bath, or to the cold douche, or to the affusion on the loins and genitals of seawater, or water in which salt has been dissolved being preferred. He should sleep on a hair mattress, and not be allowed a longer period than seven hours for repose. If he or she be much weakened, two or three hours rest on a sofa may be allowed in the middle of the day, but sleep ought not to be permitted, as it must be reserved until bedtime. The diet should be sufficiently nourishing without being heating or stimulating, and the amusements and the reading be such as will not excite sensual desires. The mind, as well as the body, ought to be fully, agreeably, and profitably occupied, without inducing more fatigue than will favour sound sleep during the hours devoted to repose.

20. During the course of this treatment, the

digestive functions should be duly promoted and the bowels regulated. Costiveness will be best prevented by means of stomachic aperients, as the compound infusions of gentian and senna conjoined, taken either early in the morning or at bedtime; and the impaired tone of the sexual organs and nervous system will be the most certainly remedied by the tincture of the sesquichloride of iron, with tincture or infusion of calumba, &c.; or by the sulphates of iron and quinine with the compound galbanum pill, or a vegetable extract; or by the iodide of iron in the sirup of sarsaparilla, or by such other preparations of iron and their combinations as the peculiarities and complications of the case will suggest. In many instances, and more especially in those which manifest a tendency to pulmonary disease, to disordered action of the heart, or to nervous headaches and affections, the *mistura ferri composita* will prove an excellent remedy; and, if there be any tendency to glandular or tubercular disease, the liquor potassæ and tincture or extract of conium may be added, or the iodide of iron or the iodide of potassium may be substituted. When self-pollution has been early or long practiced, the consequent states of anæmia and of nervous exhaustion require either an immediate recourse to chalybeates, or the adoption of them after vegetable bitters and tonics have been taken for a few days with alkaline carbonates, or with the mineral acids, according to the peculiarities of the case.—(See further the treatment advised in the article DEBILITY, § 29, *et seq.*)

21. *B. Involuntary Pollutions, or Spermatorrhœa*, generally originating in self-pollution, or in venereal excesses, require the same means as have been just advised. But these may not suffice to prevent the occasional or even the frequent recurrence of involuntary pollutions; for, although the *voluntary* emissions are discontinued, the *involuntary* may replace them in some form or other. LALLEMAND, PHILLIPS, and others have shown that the passage of a bougie, armed with lunar caustic, down to the seat of irritation, at or about the mouths of the seminal ducts, will remove this often distressing complaint. The application of the caustic is made by means of LALLEMAND's instrument, which conceals the caustic until it has arrived at the seat of pain, which is usually a little in front of the prostate, and a little more than six inches from the orifice of the urethra. When the instrument has reached this point, then the caustic is uncovered, and that portion of the urethra brushed over with it. As soon as this has been done, the caustic is again covered and the instrument is withdrawn. This application occasions little uneasiness; with slight smarting upon passing the urine, and a discharge, which is sometimes considerable, and at first is thin and watery, but gradually becomes thicker, and in the course of a few days ceases. A feeling of improvement is stated by Mr. PHILLIPS to be early manifest in most instances, but the effect of the remedy cannot be estimated until the irritation has subsided. If by the end of six weeks, he remarks, from the application, a very decided amendment, or a cure, be not produced, it may be concluded either that an insufficient application of the caustic has been made or that the fatal habit of self-pollution is still persisted in. He has more than once ap-

plied too little, but he has never had to accuse himself of having applied too much. In any case a second application is indicated when the desired effect is not obtained from the first. He has never had occasion to make more than two applications, but circumstances might render a farther recourse to the remedy proper.

22. If the affection have been caused by inflammation of the urethra—by gonorrhœa or by gleet, or if it be consequent upon stricture, it may cease upon the removal of the primary disease. But if this result be not procured, then LALLEMAND's treatment ought to be tried. When there is stricture, then the mechanical obstacle ought to be removed before this treatment is employed; but the existence of gleet need not prevent its immediate adoption. Mr. PHILLIPS states, that he has scarcely ever had recourse to a second application until five or six weeks have passed and given the assurance that the first has been insufficient. Of 109 cases, 84 were under 22 years of age; 97 admitted that they had practiced masturbation, and they referred this complaint to that cause. Every one, however, asserted that the habit had been discontinued—by some for a few months, by others for years; but in many cases he suspected the accuracy of the assertion.

23. I have been consulted by a number of persons of various ages, from seventeen or eighteen up to between fifty and sixty, who have been subject to this complaint. The most common age was from twenty to thirty-five; but almost in every case abuse of the sexual organs was confessed. In several instances the patient was married, and, in the majority of these, there was no family. Some of the patients were widowers. One gentleman, aged about fifty, married for ten or twelve years to a young and healthy woman, and has had no family, was addicted to self-pollution when young; but being of a robust constitution, and indulging in field-sports, he did not appear to have suffered. When he consulted me, he was liable to frequent involuntary discharges, and sometimes to two in one night, even although he may have had intercourse with his wife soon after going to bed. This, and similar cases, have shown that marriage, which will prove a cure of the complaint in many instances, will not always prevent its occurrence, or remove it when it depends upon chronic irritation of the mouths of the seminal ducts, and upon congestion and enlargement of the prostate gland, these morbid conditions co-existing in that case, but that it may even induce this disorder, and associated disease of the prostate, if sexual intercourse be too frequently indulged in.

24. In young and otherwise healthy persons, when the complaint has not occasioned complete impotency, although the patient may fear the existence of this state, or dread the accession of the loss of all sexual power, marriage will generally bring about the healthy state of the sexual organs, if they be very moderately and regularly exercised at the promptings of sincere affection in connexion with sexual desire. But it is always preferable that the complaint should be removed before the married life is commenced; and it should be imperative, when impotency more or less complete exists in consequence of voluntary, and its sequent, involuntary pollutions, that this state should not be

entered upon until the sexual powers are restored. When involuntary pollutions are complicated with enlargement, congestion, or inflammations of the prostate gland, or with gleet, strictures, or affections of the rectum, these must be altogether removed before marriage is advised; and in no case ought it to take place where the testes are soft and wasted, and the spermatic veins varicose, these lesions being often consequent upon, and associated with, the impotency following voluntary or involuntary pollutions.

25. Although LALLEMAND's treatment is very frequently successful, especially in the cases where irritation exists about the mouths of the seminal ducts, and in such as the one now mentioned, when it occurs in the married state, or is caused by venereal excesses, yet several cases have come under my care in which it had failed in the hands of expert surgeons; and the difficult task was imposed of removing, by strictly medical treatment, what surgical means, aided by medicine, had failed to remove. In most of such obstinate cases, the cure or alleviation of the complaint depends much upon the patient himself; for it is not alone sufficient that he has relinquished the vice in which the evil originated, but it is also requisite that he should so regulate the state of his feelings and passions—so direct his mind, as not to encourage sexual desires, and not to contemplate its disgusting consequences, as either kind of mental rumination will only increase the evil. It will generally be far preferable for the patient to promote his general health and strength by regular living, and by regular and sufficient occupation, mental and bodily, avoiding fatigue and *ennui*; to regulate and promote the several digestive and assimilating processes; to increase the tone of the sexual organs by the means suggested above (§ 19, 20), and to proceed patiently for a time in this course, without injuriously exciting his imagination and desires, and as injuriously directing his attention to the disorder. During a life of celibacy, the discharge may occasionally occur without material injury; and as long as it is not productive of debility, of pains in the back and loins, or weakness of the limbs and joints, or other disorder, and does not recur often, or more frequently than once in ten days or a fortnight, the injury done to the constitution will not be great.

26. It has been supposed by some physicians that the occasional occurrence of involuntary emissions must necessarily occur to a man who is perfectly continent. This is certainly the case very generally if the individual have devoted himself to self-pollution in early life, or been married, or been addicted to sexual intercourse, and has afterward become continent; but a person who has lived chastely during puberty and subsequent manhood, and occupied his mind and body rationally and usefully, without indulging prurient ideas, may pass these, the most likely epochs of life to be subject to this complaint, without experiencing it. The seminal fluid is secreted, nevertheless, and collects in the seminal vesicles; but as the susceptibility of these parts and of their associated organs is neither weakened by abuse, nor inordinately increased, nor unnaturally excited so as to produce the venereal orgasm, no abnormal discharge of it takes place, although the vesicles

continue charged, absorption of the secretion taking place co-ordinately with its elaboration; and thus, instead of proving *excrementitious* and weakening the frame by its absence or loss, it is actually *recrementitious*, and promotes nervous power, the cerebral manifestations, and all the organic and assimilative functions.

27. In young persons, especially those who indulge prurient ideas, or have devoted themselves to weakening self-pollutions or venereal excesses, the constant or frequent desire excites the sexual organs, distends the seminal vesicles, and augments the prostatic secretion, so that the simple contractions of the sphincters after fæcal or urinary evacuations, or the passage of hardened fæces, press out a portion of the contained fluids, which is partly, at least, seminal, as shown by the presence of spermatozoa, and partly prostatic, mixed with the last drops of urine from the membranous part of the urethra, when passed after micturition. In this class of cases the disorder ceases upon a due regulation of the mind, of the feelings, emotions, &c., and after the mind and body are duly and healthily employed. For these, especially when no disease of the prostate gland is present and the testes are quite natural, marriage may be safely advised. Although the patient may suppose himself almost impotent, owing to the prevalence of the discharge, and may actually be so for a time from his fears, or the impression on his mind that he will be found incapable, yet after marriage his fears subside, his powers return, and no longer is any sexual deficiency or disorder complained of.

28. It is often necessary, both as respects the mind of the patient and as to his scruples respecting marriage in his existing state, that medical treatment should be adopted, and some amendment procured before this state is entered upon, or even without reference to this state. If the means and regimen above advised (§ 19, *et seq.*) fail after a due trial, other remedies should be prescribed. The muriated tincture of iron is usually recommended with the *tinctura cythæ*, but they often fail; and in many cases the latter tincture is not appropriate. I have often given the former with the compound tincture of camphor and the infusion or tincture of *calumba*, and sometimes with decided benefit. When, however, there is pain or heat about the anus, with uneasiness or fulness in the perinæum, or any indication furnished by the excretion of urine or of fæces, of irritation about the seminal ducts or prostate gland, or congestion of the latter, or any affection of the rectum, then local depletions from the perinæum and anus, soothing and gently aperient clysters, and much of the treatment I have advised for inflammation of the PROSTATE GLAND, should be adopted. I some time ago attended a case of successive self-pollution, involuntary seminal discharges and retention of urine, in which I had the excellent aid of Mr. FEROUSSON. In this case there was superinduced, at an early age, enlargement of the prostate, spasmodic stricture of the urethra, mental weakness, and, as often seen in similar cases, the most cowardly fears of the introduction of a bougie. The nature of the complications, the habits of the patient, and his defective self-control, rendered both medical and surgical treatment only partially successful. In the simpler

cases, and where debility and susceptibility of the parts are the chief causes of the complaint, the tonics and stimulants already mentioned, the tincture of iodine in small and very gradually increased doses, the iodide of iron; a cautious trial of powdered nuxvomica or its extract or tincture, or of strychnia, or of stramonium; a recourse to blisters over the perinæum or over the sacrum; the application of the emplastrum thuris compositum over the loins; and various other restorative remedies, may be severally advised.

[We have found *ergot*, given in the form of powder and pill, very efficient in checking and controlling these discharges; nor is it less efficacious in relieving irritation of the urethra and prostate, on which these involuntary emissions so generally depend. Dr. C. L. MITCHELL, of Brooklyn, New York, has reported to us two very striking instances in which spermatorrhœa was cured by this agent after the other usual remedies had entirely failed. Its *modus operandi* is doubtless through the mediums of the lower portion of the spinal cord and the lumbar and sacral nerves thence proceeding; hence its efficacy in all diseases of irritation, congestion, and perverted secretion of the organs seated in the pelvic cavity.]

29. If the complaint be associated with ascariæ in the rectum, or with hemorrhoids or other disorders of the rectum, these complications should be removed by the treatment appropriate to them. Pills containing the sulphate of iron, camphor, and asafetida may be taken, and afterward oleaginous clysters, with salt, camphor, and asafetida, may be occasionally administered for the removal of worms; and associated disease of the *prostate gland* and *hemorrhoids* should be treated as recommended under these heads.

[The remarks of Mr. PHILLIPS, referred to by our author, are so important, and the disease of which he treats is becoming so prevalent, that no apology will be needed for presenting the substance of his essay.—Ed.]

"Involuntary discharges are for the most part, if not altogether, caused by irritation set up in or about the ducts connected with the testicle. In some cases it may be doubtful whether the irritation by which they are excited may not have its seat in the rectum; primarily there is no doubt it may, but other cases would lead to the supposition that secondarily the mucous membrane of the urethra itself may suffer, and that, when the irritation in the rectum has ceased, that of the urethra may still keep up the mischief.

"There are particular modes in which the urethra irritation is commonly excited; among these, masturbation holds a prominent place; by this practice the constant excitement of the seminal ducts ends by establishing a permanent irritation there; it may likewise happen from excess in sexual intercourse. Next to this cause we arrange gonorrhœa or gleet discharges, which, from time to time, establish chronic inflammation in the vicinity of the orifices of the ejaculatory ducts. Then follows stricture, which, by opposing an obstacle to the free passage of urine, ultimately causes the development of a morbid condition of the mucous membrane between the stricture and the bladder. The same state of these organs may re-

sult from irritation within the rectum; that irritation may be caused by fissures or piles, or by the presence of ascarides.

"It is said that other causes are capable of inducing the same disordered action of the sexual organs, but as I profess in this place merely to point out such as have come within my own observation, I do not propose to consider others.

"The mode in which the irritation, once set up around the orifices of the ejaculatory ducts, acts, is very much the same as obtains upon the application of irritation to the mouths of other ducts; it solicits increased action in the organ with which they communicate. Irritate the bladder, and the kidneys are stimulated to increased action; irritate the conjunctiva, and the lachrymal secretion increases; irritate the duodenum, and it is said bile will be supplied in increased quantity: it is unnecessary to carry the illustration farther.

"How does masturbation induce this irritation? Within moderate limits it would not do so; but if you give any canal too much to do, you will ultimately develop irritation in it, more especially at its orifice. If urine be passed too often, in cystitis for instance, the orifice of the urethra becomes red, and the same thing happens to other conduits: it is in this way that masturbation or sexual excesses may develop irritation at the mouths of the ejaculatory ducts; it is in that way increased secretion is determined in the testicle; and thus involuntary discharges, consequences of masturbation or excesses, is explained.

"It is easy to explain how gonorrhœal discharges may induce a similar state of things; in many cases, and especially when the discharge is obstinate, the inflammation upon which it depends is extended backward until it reaches the neighbourhood of the prostate; where it may excite, on the one hand, the kidneys, on the other the prostate, and on the third the testicle, inducing each of those organs to furnish more than its accustomed supply. That the inflammatory action, under these circumstances, is likely to fix itself there, is shown in two ways: the existence of stricture so commonly near that region, and the acute pain experienced beyond the curvature when a bougie is passed. Often the inflammation may extend to the bladder itself. Often it passes along the spermatic ducts to the testicle.

"When the involuntary spermatic discharges are caused by stricture of the urethra, the immediate exciting cause is the same as when they are consequences of other circumstances; irritation of the mouths of the ejaculatory ducts. The irritation is then caused by the obstacle to the passage of the urine, and a state of chronic inflammation may be developed along the mucous membrane from the stricture to the neck of the bladder, and may even extend into that organ, or along the ejaculatory ducts. Irritation within the rectum, when long continued, may extend to the sexual organs, and occasion the discharges which we are considering. In some cases the source of irritation of the sexual organs may continue to be confined to the rectum, and when that ceases the spermatic trouble may also cease; but in other instances the spermatic disturbance may persist after the irritation of the rectum is cured. There is no

difficulty in accounting for this circumstance; the irritation, originally anal, has ultimately become urethral also, and will only yield to treatment directly applied to that part. Every experienced surgeon has had ample opportunities of observing the intimate sympathy which exists between the bladder, and the urethra, and the rectum. How an irritable bladder may make an irritable rectum; how piles, or other affections of the rectum, will occasion trouble in the bladder; how the application of caustic within the urethra will now and then induce spasm of the rectum; how, in the efforts made to empty the bladder, in many cases of stricture, a corresponding effort will be made by the rectum; it may not always be easy to explain, but they are facts commonly observed. In most cases the evidence of involuntary spermatic discharges is clear enough, but the time comes when the ejaculation is unaccompanied by the ordinary sensations, and the patient may then be unaware of the extent of the evil. I have again and again known cases where the spermatic fluid passed out with the urine; others, in which the efforts at stool caused a pressure to be made upon the distended seminal vesicles, and thus their contents were squeezed out; but the fluid may not pass until the process of buttoning up is going on, and the evil may be undiscovered. Still, unless the disorder be very advanced, in most cases the person himself is aware of it when it passes with the urine, because it almost always passes with the last drops, and can then be detected, and because a certain sensation is experienced about the neck of the bladder. But when the medical man is consulted, he calls for the recently passed urine, or requests that it may be passed in his presence, and at the bottom of the vessel he perceives small granular diaphanous particles; and they are seen floating even before the urine cools; if the evil be, however, very advanced, no peculiar sensation is experienced, and the granular matter may be undetected, and may assume a more uniform cloudy appearance. In cases where uncertainty remains with regard to the deposit, we may advantageously have recourse to the microscope, by means of which the little long-tailed animalcules of the spermatic fluid can readily be perceived. Under any debilitating causes, whether those causes be found in frequent spermatic discharges, disease, or old age, the fluid becomes much thinner, and the animalcules much less numerous, and they may be almost, if not altogether wanting.

"One of the general symptoms resulting from too frequent spermatic discharges, which is most distressing to the sufferer, is a state approaching to, if not at the time, actual impotency. It is not that the seminal fluid, though deteriorated, is incapable of determining fecundation, but it is that the organs are wanting in the energy necessary for projecting the fluid into the uterus; the erection of the penis, if it exist at all, being only momentary. The digestive functions become deranged; the bowels constipated; nutrition languishes; respiration is troubled; the voice fails; the heart's action is interfered with, even to such an extent as to induce the belief of actual disease in that organ, and hypochondriasis becomes complete. These things do not advance far without caus-

ing trouble in the nervous system, manifested by some perturbation of the senses, by headache, with great sense of weight or pressure, and they are accompanied by loss of memory; a timidity and apprehension which are very painful.

"It must be evident to every one who takes the trouble to reflect on these things, that as the causes of these discharges are many, the treatment must also be variable. When the irritation is in the rectum, the case will require a very different course of treatment to one proceeding from stricture of the urethra. We will, therefore, make such general remarks as are proper with reference to the treatment of the several varieties of the affection which we have considered. First, when the cause is masturbation or sexual excess: The causes here are voluntary; the cure must also be voluntary. Lunar caustic will be powerless unless the patient has sufficient determination to abstain from the practice. But in many cases perfect abstinence will not suffice to put an end to the mischief; the *voluntary* discharges are got rid of, but they were persisted in so long that permanent irritation has been set up in the verumontanum, and that irritation may, as we have already explained, excite equally injurious *involuntary* discharges; and here a remedy must be found by the surgeon. The first thing we have to do is to introduce cautiously a bougie, to pass it down towards the bladder; but before it arrives there, the patient will complain of pain, which is sometimes very acute; and the point at which the bougie has then arrived is usually a little in front of the prostate. The surgeon must then carefully observe how far the penis has been extended, and a mark must be made upon the bougie to indicate the depth to which the instrument has penetrated, because that is the point upon which the lunar caustic must be applied. The depth to which we must penetrate must be marked upon the caustic instrument, which is then introduced and gently passed to the proper point, when the caustic is uncovered and the membrane brushed over; as soon as that has been done, the caustic is again covered, and the instrument is withdrawn. In some cases the patient complains of a little heat when the caustic is applied; in others, the sensation spoken of is a coldness. I have more than once known some discomfort, almost amounting to spasm, at the anus, but altogether it is astonishing how rarely any complaint is made. At the next time of passing the urine, more smarting is usually experienced; it may continue through the day, but it is very bearable. In all cases it occasions a discharge, which is sometimes considerable, and at first is thin and watery, but gradually becomes thicker, and in the course of a few days ceases. In a few cases the discharge is at first streaked with blood; and in a few rare instances there may be trifling hemorrhage.

"In most instances a feeling of improvement is early manifest, but the complete effect of the remedy cannot be estimated until the irritation has entirely subsided. Indeed, the amendment is almost always progressive, and frequently it happens that when, by the end of the second or third week, not much benefit has been apparently derived, we are astonished by the change which has been brought about in another fort

night. If by the end of six weeks from the first application a very decided amendment or a cure be not produced, we may conclude either that an insufficient application of caustic has been made, or that the fatal habit is still persisted in. It has more than once happened to me to apply too little, but I have never had to accuse myself of applying too much. In any case a second application is indicated when the desired effect is not obtained from the first. More than two applications I have never had occasion to make; but I can easily conceive that circumstances might render a farther recourse to the remedy proper. How the lunar caustic acts in extinguishing the morbid sensibility of mucous surfaces I cannot tell, but of its virtues in this respect few surgeons can be ignorant. Every day we apply it to modify the painful irritability of ulcers, as well as that of certain affections of mucous membranes. If the affection has been caused by a gonorrhœal or gleet discharge, the treatment must be the same as in the former instance.

"If it has been caused by stricture, we must first restore the canal to its natural diameter; and it may be that the morbid state of the mucous membrane behind the stricture will gradually improve when the obstacle to the passage of the urine is removed, and that with the cessation of that morbid state may also cease those spermatic discharges which have been caused by it. But this conclusion is not inevitable; the obstacle to the passage of the urine may be removed, but the morbid condition of the posterior part of the canal, which has resulted from it, may persist; so may the specific discharges. Then the efficacy of the lunar caustic can be at once demonstrated; and a single proper and sufficient application of the remedy, with the precautions already indicated, will, in most cases, promptly cure the disease of the urethra, as well as that of the spermatic organs.

"If the discharges be determined by irritation of the anus or the rectum, appropriate means must be used to cure the intestinal disorder; and it may be that when that has ceased, the spermatic disorder will also cease. But it may persist, because a distinct irritation may have been determined in the urethra by the long-continued action of that of the intestinal canal; and to dissipate that, recourse must be had to the lunar caustic, under the same restrictions as have been already pointed out." *Medical Gazette*, Dec. 23, 1842, p. 452.

"Case 1 was a young man, aged 22, addicted to excessive masturbation, often twice a day, with frequent involuntary seminal discharges. The consequence was, complete derangement of the whole system; the sexual organs were extremely lax, the structure of the penis offering no feeling of elasticity when pressed between the fingers, and the scrotum almost as thin as a piece of linen cloth, the testicles hanging very low. On passing a bougie beyond the curvature, he screamed out, and this being the seat of sensibility, the lunar caustic was applied, as above directed, with the happiest effects. It was necessary to apply the caustic only once. Case 2 was a gentleman, aged 35, who formed an intimacy with a lady of rank in Russia, whose propensities were still stronger than his own. The consequence was, the most unbridled excess in sexual indulgences. On his return to

England he formed a similar connexion, which he only gave up when he found his health giving way. The seminal discharges were constant. On passing a bougie along the urethra, it was sensitive throughout, but especially so at a point in the neighbourhood of the prostate. In two days a bougie was introduced, in order to accustom the passage to the presence of a foreign body. The caustic was then cautiously applied without much inconvenience. In the succeeding three weeks the discharge only occurred twice, once in the first week, and once in the next fortnight. The case went on well in this respect, but he died of phthisis afterward.

"Cases 3, 4, 5, and 6 were nearly of the same character, with variation as to the cause; in all, however, the involuntary seminal discharges formed the chief feature in the disease with some tender part of the urethra. The caustic was invariably beneficial. Mr. PHILLIPS ends his valuable paper with the following remarks:

"1st. It is necessary that the habits which have led to those discharges should be discontinued; any means will be powerless if the practice be persevered in. 2dly. When the primary cause of the affection has ceased, it is necessary to examine the urethra with an exploring instrument; and for the purpose I prefer an elastic catheter. The point where the pain is most acute must be accurately noted. The instrument must then be passed on carefully until urine passes along it. Observe how far it has penetrated, and having noted this, you must arrange your caustic apparatus so that it shall not reach so far by an inch, because the prostatic portion of the canal is not commonly implicated in the irritation. The point upon which the caustic is to be applied is, as near as practicable, about the region of the orifices of the ejaculatory ducts.

"It may be asked, why pass the instrument on to the neck of the bladder at all, and why state that an inch in front of the neck of the bladder is the point beyond which the caustic instrument shall not penetrate? Why, again, the spot where acute pain is indicated, during the passage of the bougie, may not be regarded as the proper place for applying the caustic? In many persons the urethra is very sensitive, and the patient complains so frequently, that a little difficulty is experienced in deciding with that test; but when you have ascertained that from the orifice of the urethra to the neck of the bladder is seven inches and a half, and when you farther find that in the passage of the bougie the most acute pain was experienced at a little more than six inches from the orifice, you can then, with much confidence, cauterize the space between the sixth and seventh inches, satisfied that the orifices of the ejaculatory ducts will not escape. It may be thought by some persons that all these precautions are unnecessary; this may be true; but off-hand surgery I dislike; and if in one case, by the neglect of such attention, I cauterized the neck of the bladder, and in another case applied the caustic entirely in front of the seat of mischief, my conscience would not acquit me of blame.

"The foregoing precautions having been taken, the caustic must be exposed, and slightly revolved along the floor of the urethra for half a minute, without fear of harm, and rarely does it excite much pain; very rarely, indeed, does

the patient complain of it. A few days ago I passed a bougie very gently along the urethra of a young man, but it produced syncope. When the caustic was applied a few days afterward, the morbid sensibility was immediately blunted. Usually a smarting is experienced when the urine passes along the urethra after the caustic is used, but it rarely continues troublesome over twenty-four hours.

"Before that time usually a thinnish discharge comes on, which may be profuse, and may be, though very infrequently, streaked with blood. After a few days it begins to abate, and by the time it has ceased the change for the better in the patient's condition seems strikingly manifest. It is always necessary to guard the patient against impatience, because four or five weeks will, in some cases, pass before the beneficial effects of the remedy become clearly evident; and this is the more necessary, because he looks with intense anxiety to the result; and sometimes it happens that a single discharge, after the application of the caustic, will dash the eup of hope from his lips, and induce the most gloomy forebodings. I may again repeat what I have said before, that I have never applied too much caustic, but I have more than once failed by using too little; and much experience is necessary to apply the proper dose. However, it is better to err on the safe side, until experience shall have given confidence in the use of the remedy. I have scarcely ever had recourse to a second application until five or six weeks have passed, and given the assurance that the first has been insufficient."—*Medical Gazette*, Dec. 23, 1842, p. 452, and Jan. 20, 1843, p. 586.

"Since the publication of these remarks by Mr. PHILLIPS, the treatise of M. LALLEMAND 'On Involuntary Seminal Discharges' has been reviewed in the British and Foreign Medical Review, but as the treatment therein recommended is very similar to that adopted by Mr. PHILLIPS, we need not again dwell upon it. The reviewer remarks, that M. LALLEMAND may possibly be surprised that the armed bougie was adopted in similar, if not identical cases by Sir EVERARD HOME more than forty years ago. The following is the experience of three British surgeons on this subject, communicated to the reviewer by letter. One gentleman writes as follows:

"I can recollect eleven cases in which I have found LALLEMAND's treatment successful, and one in which I did not completely succeed. In seven of the eleven cases a single application of the caustic was enough; in four it was necessary to apply it a second time; in a single case two applications were insufficient to cure the disease, although the improvement was very great. The effects are immediate. A person in whom the discharge has continued for some months, will have none for some days after the use of the caustic; but in some cases, as the irritation subsides, it will come again."

"I have carefully noted," writes another gentleman, "twenty-seven cases treated by the nitrate of silver, either applied in the solid form to the prostatic portion of the urethra, or used in the form of injection. Of these cases, thirteen were completely cured; eight so much benefited that the emissions only returned occasionally, and produced but little effect on the

system; and the remaining five benefited by the period between the emissions being lengthened, though not to the same extent as the cases in the second series. The application of the solid nitrate, in many cases, produces very great irritation, sometimes complete retention of urine for a short period; in others, inflammatory irritation with bloody urine, lasting from eight to ten days, and even longer. These circumstances lead me to use solutions of the salt, one or two grains to the ounce, advising the patient to inject several times, at intervals of three and four hours, till a marked irritation was brought on; then to discontinue the remedy for a time, and to have recourse to it again, if the cure was not effected, when the irritation has subsided. The injections used in this way produce often great irritation and bloody urine, which continue sometimes many days. They have, however, in almost every instance, a beneficial effect upon the emissions."

"A well-known and experienced Scottish surgeon observes, 'With regard to LALLEMAND's method of eauterizing the urethra, I have tried it in above a dozen cases, and in the majority of them with decidedly good effects. In those distressing cases of irritability of the bladder where the prostatic portion of the urethra is chiefly affected; in certain cases of chronic disease of the mucous membrane of the bladder, and in that very prevalent and debilitating complaint to which young men are subject, nocturnal emissions, the efficacy of the practice is sometimes very striking. In the latter case, when the eauterization of the prostatic portion of the urethra fails, I have been lately in the habit, from a knowledge of the very intimate sympathy subsisting between the parts, of applying the cautery to the external orifice of the canal, and for about an inch down, and I think, in some cases, with more decided advantage.'

"The last communication we shall quote is the following: 'I have employed the caustic in several cases in private and at the hospital, and I entertain a very favourable opinion of its efficacy; indeed, in some instances, its good effects have been quite remarkable. I have used it successfully in cases of seminal emissions from self-abuse, sexual excesses, or in case of obstinate onanism, which affections appear to be attended with, and partly kept up by a morbid state of the prostatic part of the urethra. After using the caustic, I have found benefit from small doses of cubeb powder (gr. x-xxx.) combined with the tincture of hyoseyamus, and also from steel medicines; the patient practicing, of course, the most rigid self-denial in respect to the cause of the complaint. The patients upon whom I have employed the caustic have not experienced the severe effects described by LALLEMAND as 'occasionally' resulting from it. The application which I make is always slight and transient, and the effects of it subside in a day or two. I have never had occasion to apply leeches to the perineum afterward, and in no case has swelling of the testicles been produced by it. The hip-bath and rest is all the treatment usually required; but I am generally obliged to make two or three applications of the nitrate of silver, and sometimes more, before the complaint is wholly removed."

"In regard to caustic injections, as practiced

by the gentlemen whose notes we have quoted second and third, we have ourselves had no experience in *this* complaint, though, of course, in common with every practitioner, we have, times without number, ordered them in gonorrhœal and blenorrhagic discharges. We are disposed to think that the former of these two gentlemen considerably overstates the effects of cauterization as they usually manifest themselves, and we are also disposed to believe that the application of the solid caustic to the deep part of the urethra is less irritating and more effectual than the application of it in solution, and to the outer part of the urethra.

"The space which M. LALLEMAND usually cauterizes is from the neck of the bladder to the membranous part of the urethra; but sometimes he brushes over the internal surface of the bladder itself to a greater or less extent. He cautions us strongly against repeating the operation too soon; and advises us to wait two or three weeks before we reapply the caustic. Many of his cases appear to have been cured by a single application. Pain, and a slight discharge of blood, but never amounting to hemorrhage, seem to have followed some of his operations; but these consequences disappeared at the end of from twelve to forty-eight hours. In one case they are described as lasting three weeks, but this is mentioned as a rare exception. When the emissions have been diurnal, M. LALLEMAND regards the conversion of them into nocturnal, and the fact of the emissions being once more accompanied with erections and with pleasurable sensations, as a sign of the favourable effects of treatment and prospect of cure.

"We shall now, with great brevity, advert to other modes than cauterization, of treating involuntary seminal discharges, depending solely on chronic inflammation of the prostatic portion of the urethra and of the vesiculæ seminales. The daily introduction of a bougie, and the retaining it for a longer or shorter time in the urethra, may first be mentioned. This, as our own observation enables us to testify, is often useful. Leeching of and blisters to the perineum are by no means of slight efficacy, especially where the prostate is tender and enlarged. We have also prescribed tartar-emetic frictions of the perineum with excellent effects. A total abandonment of masturbation, and a moderate use, or even an entire though temporary disuse of coition, are, of course, indispensable measures. One of our correspondents states, that he has found opiates extremely useful. They are so in most cases, though not in all, since they sometimes seem to augment the disease. Conium is safer; and both it and opium may be used both constitutionally and as a suppository. Cold clysters are often of benefit. As regards general means, alcoholic and malt liquors must be abandoned. M. LALLEMAND's opinion of these is exceedingly hostile; and we believe he is right in this. The food should be nourishing, light, and unstimulant; the bowels should be, of course, attended to, and, as a general rule, country air and exercise prescribed. Among medicines and articles of diet, tea and coffee in excess, tobacco, camphor, nitrate of potash, aloes, must be abstained from."—*British and Foreign Medical Review*, April, 1843, p. 357.

We have been politely favoured with the

following letter, on the treatment of spermatorrhœa, from our friend, Dr. F. CAMPBELL STEWART, of this city, whose very extensive experience and success in the treatment of the disease is generally known to the profession, and our limited experience in its management leads us to the same conclusions as expressed by Dr. S.—ED.

"I have used LALLEMAND's instrument, and pursued his method of treatment for involuntary emissions for several years, and I am decidedly of opinion that it is preferable to any other that I know of. My own modification of the original *porte caustique* (described with a wood-cut in the xxiii. No. of HAY's *American Journal*, &c., July, 1846, p. 265) I have used exclusively for three years past, and I think it possesses several advantages over that of LALLEMAND.

"The number of cases of this disease in which I have cauterized exceeds fifty, and the result has been almost uniformly successful. I allow the caustic to remain in contact with the prostatic portion of the urethra for from thirty seconds to one minute, and never for a longer period. My patients are always prepared for the operation by the frequent introduction of wax bougies, and they are kept quiet for a day or so after each application of the nitrate of silver. I have very rarely had to repeat the operation more than three times, and always allow an interval of from one to three weeks between each application.

"The result of my experience is entirely satisfactory, and the caustic has failed in three or four cases only, and these were aggravated. Accidents have ensued once or twice. I have had one troublesome hemorrhage (within six hours after operation), and abscesses have formed in two cases at the margin of the anus, which were very painful and tedious of cure. The patients ultimately recovered, however, without fistulæ or any other unpleasant consequences ensuing.

"I have tried most of the other means recommended in this complaint—pressure, leeching, camphor, potassa, &c., &c.—but without any marked benefit; and, with the exception of a combination of camphor and extract of lettuce, which I generally give my patients in small doses, and at night, when they are undergoing the caustic treatment, I consider them as almost wholly useless.

"I find the disease to be very common among the middle-aged and young men of our country, particularly those belonging to cities; and I have more than once treated married men for it.

"As to regimen, clothing, exercise, dancing, &c., I always advise my patients to pursue the course that is universally recommended as preventive of the unfortunate habit of onanism, which is undoubtedly the most fruitful of all the causes of spermatorrhœa. A Dr. KAULA, of Paris, who was formerly a pupil of LALLEMAND, has recently published a quarto volume on the subject of this disease, accompanied with the details of a vast number of cases. His experience confirms all that I have said of the caustic treatment, which he considers the only means by which a radical cure can be obtained. We also agree in our views in regard to the serious and distressing nature of the malady, the anxiety and misery occasioned by which can scarcely be exaggerated."]

PREGNANCY.—THE PATHOLOGICAL AND THERAPEUTICAL RELATIONS OF.—DISORDERS INCIDENTAL TO PREGNANCY.

CLASSIF.—GENERAL PATHOLOGY.—*Semciology*.—GENERAL THERAPEUTICS.

1. A change is produced in the uterine organs by impregnation, which affects, sympathetically, the female constitution variously, according to temperament, diathesis, habit of body, predisposition, and age. The more constant and slight changes may be viewed as *physiological*, or as the natural and healthy consequences of the new action imparted to the uterine organs; those which are characterized by more or less derangement of function may be, with equal justice, considered as *pathological*. But there are other considerations besides these which relate to the physiological and pathological relations of pregnancy that will engage the mind of the physician when he is required to treat these disorders, to which pregnancy may predispose, or which it may more directly occasion; and these considerations have strict reference, not only to the treatment required in the particular circumstances of the case, but also to the effects which such treatment may produce upon the state and progress of utero-gestation. Moreover, the pregnant female is not only liable to certain disorders incident to this state, but also to others, in common with the species—to other maladies which attack all who are exposed to their causes. Even in the course of several chronic diseases pregnancy may take place, with or without modification or change of that progress and termination; and thus the pregnant state is most important in respect of the course, termination, and treatment of diseases which occur

during its course, as well as of those which had previously existed. The propriety, therefore, of devoting due consideration to the subject cannot be disputed. I have, however, to regret that my limits admit only of a very succinct account of the several topics which the subject comprises.

2. I. THE LOCAL AND SYMPATHETIC CHANGES CONSEQUENT UPON PREGNANCY.—Impregnation induces a remarkable change in the state of the uterine organs. The nerves with which these organs are supplied experience a more continued state of excitement, and probably even an increased development. The blood-vessels and lymphatics increase in size, and their actions are augmented; and while these organs become generally more vascular and more excitable, the uterus itself augments in volume with the progress of the contained embryo. The ganglia and plexuses supplying the sexual organs are intimately associated, as I have shown in the article SYMPATHY, and in the CROONIAN LECTURES (*published in the Medical Gazette*, vol. xl.) by means of communicating branches of nerves, with the other ganglial and sympathetic nerves, and with the spinal cord and its nerves, both sensory and motory, with, in fact, the ganglial and the cerebro-spinal nervous systems, from both which these organs derive their energies, and upon, as well as through the media of, these systems, they produce their numerous and varied sympathies. That the uterine nerves, plexuses, and ganglia experience, with the development of the ovum of the uterus and of the uterine vessels, an augmentation of their size, was an opinion entertained by W. HUNTER, and subsequently confirmed by TRIEDEMANN and R. LEE. With this remarkable increase of vital action, and of material or structural development of all the constituent tissues of the organ, a more exalted degree of sensibility is imparted, through the media of the organic and cerebro-spinal nervous systems, to the whole frame, which thus participates, more or less, in the excitement and vital activity of the uterus.

3. When it is considered that during pregnancy the uterus, and, consequently, its constituent tissues, are undergoing a process of development, which Dr. MONTGOMERY has shown to amount, at the full period of utero-gestation, to 519 times its virgin capacity, and to twelve times its solid substance, it cannot be a matter of surprise that so remarkable a change should be attended by numerous sympathetic phenomena, and that this organ, having become the centre of most important vital actions, should also be the source of various influences and derangements, manifested both by adjoining and by remote parts, during the progress of that change and of the development of the embryo with which it is associated. The remarkable increase of the functions of assimilation, circulation, and nutrition observed to follow the appearance of puberty is often exceeded during pregnancy; the excitement of the uterine functions, tending more remarkably, than the first evolution of these functions, to develop all the vital actions and manifestations—to increase the general sensibility and susceptibility, to augment vascular fulness and plethora, and to promote the several secretions and excretions, excepting that excretion furnished by the uterus itself. As consequences of these sym-

pathetic changes, and of various predispositions depending upon temperament, diathesis, habit of body, and previous disorder, numerous ailments arise in the course of pregnancy, as well as others which this state is not concerned in producing.

4. Other disorders also occur in the progress of pregnancy, which depend, more or less, upon the mechanical influence which the increased size of the uterus exercises upon the adjoining viscera, and probably also upon sympathetic excitement, or upon irritation, caused by vascular determination to this organ. As the uterus enlarges within the pelvis, the rectum, neck of the bladder, and urethra experience increased pressure, and some disorder of the functions of excretion is often thereby produced, with pain in the back, and various sympathetic affections of a transient or varying character. As the uterus enlarges farther and rises above the brim of the pelvis, the urinary bladder is often pressed upon so as to diminish its capacity, and to occasion frequent calls to pass urine, or even some degree of incontinence of urine. When the womb has nearly or altogether acquired its utmost size, the mechanical effects produced by it may not be limited to the abdominal viscera, but may extend to the thoracic cavity, occasioning thus disorder of the functions of one, or of several organs. The stomach, duodenum, biliary organs, kidneys, and colon have their functions impeded or disordered; and indigestion, jaundice, constipation, and pains in the back and loins, and changes in the state of the urine are often complained of. The mechanical disturbance extends upward, the diaphragm being pressed so high as to diminish the thoracic cavities, and to disturb the functions of the lungs, and sometimes also of the heart, occasioning dyspnoea, short breathing on slight exertion, and embarrassed circulation through the cavities of the heart. The pressure, also, upon the veins and absorbents within the pelvis occasions a varicose state of these vessels, oedema, pains of the limbs, numbness, or neuralgic affections. In some cases, especially in females having a small pelvis or abdomen, or who have borne several children, the muscular and integumental parietes become relaxed or pendulous, admitting of malpositions of the uterus.

5. II. AFFECTIONS OF THE UTERINE AND GENITAL ORGANS AND OF THE MAMMÆ, CAUSED BY PREGNANCY.—DISORDERS OF RELATED PARTS.—i. **ŒDEMA OF THE LABIA VULVÆ** occurs chiefly in females far advanced in pregnancy—during the 7th, 8th, and 9th months. It disappears immediately after delivery, and is caused chiefly by the pressure of the gravid uterus, especially when descending into a large pelvis. It is much augmented by a sitting or standing posture, and is characterized by a tense, colourless swelling, of equable density, often pitting on pressure, and by absence of throbbing and of increased heat. The œdematous labia may be attacked with erysipelas shortly before or after delivery, and the utmost danger, or even death, may result; or they may be the seat of simple excoriations.

6. *Treatment.*—A mild aperient, repeated occasionally, the recumbent position, and bathing the parts with a suitable lotion, will generally remove the affection. In some instances, diu-

retics may be necessary; or even puncturing the œdematous parts, so as to allow the discharge of the fluid. If inflammation or erysipelas occur, the treatment should depend upon the peculiar features and circumstances of the case.

7. ii. **PRURITUS OF THE VULVÆ.**—This is often a very troublesome affection, and frequently connected with a leucorrhœal discharge [ascariides in the rectum], or with an aphthous state of the vulva and lower part of the vagina, or with a state resembling an eruption of small papulæ. It is generally referable to the active vascular determination to the sexual organs, consequent upon impregnation.

8. *Treatment.*—Lotions of acetate of lead, [hydrocyanic acid], or of nitrate of silver have usually been prescribed for this affection. I have generally added a little vinum opii to these. Lotions consisting only of tar-water will generally prove efficacious. In the summer of 1826 I was consulted by a surgeon in an obstinate case, for which the usual means had been employed. I advised a saturated solution of borax in rose-water; and this proved successful. Since that time I have generally prescribed this substance for similar cases. Dr. CHURCHILL states, that a decidedly antiphlogistic treatment may sometimes be required; as venesection, leeches applied to the vulva, and one or two smart purgatives. [Sometimes the stramonium, belladonna, or creasote ointment will succeed in affording relief.]

9. iii. **LEUCORRHEA** is generally caused by the increased determination of blood to the uterine organs during pregnancy, and probably, also, in part, by the pressure of the gravid uterus. It sometimes occasions great debility, and increases the aching of the back often complained of during pregnancy. It may, when excessive in the early months, cause abortion; but at an advanced period it is not very injurious, otherwise than by producing or increasing debility.

10. *Treatment.*—The propriety of removing or suppressing this discharge ought to be considered before any treatment is ordered for it. In many cases, the inconvenience is not so great as to require treatment. But in some instances the discharge is so exhausting as to require to be moderated, if not altogether arrested. To strong, plethoric females, and where the disorder proceeds from active determination of blood to the uterine organs, a moderate venesection and cooling aperients will prove beneficial. In weak or delicate females, and when the digestive organs are disordered, the bitter infusions, as those of cheyreira or of calumba, with small doses of the muriated tincture of iron, or with a mineral acid, will be of service. If the discharge occur in connexion with any pulmonary affection, it may be moderated by internal remedies; but it should not be arrested by powerful astringents. (See art. **LEUCORRHEA.**)

11. iv. **MENSTRUATION DURING PREGNANCY**, or, rather, a periodical discharge of a sanguineous fluid from the vagina, have been occasionally observed. This discharge may occur once or oftener during utero-gestation, and after irregular intervals, but it most frequently takes place at the menstrual periods, and in some instances it returns for three, four, five, or six months, or even for the whole period of pregnancy.

DRS. DENMAN and HAMILTON have doubted the occurrence of these discharges, a skepticism the more remarkable considering the great experience of these physicians, and the frequency of the phenomenon according to the observation of very eminent practitioners. Although I have never been engaged in the practice of midwifery, yet I have been consulted in two cases in which this discharge was stated to have occurred regularly during four or five successive menstrual periods; and not in one pregnancy only, but in each of several occasions of utero-gestation. Neither of these patients had ever had an abortion. The discharge was represented to have continued from three to four days, to have become paler than usual after the second day, and to have passed into a moderate leucorrhœa. It does not appear to be attended with any inconvenience to the patient beyond increased aching of the back and loins. The growth of the child is not affected by it; although, judging from the instances which I have seen, the constitution is rendered more delicate; so that the aphorism of HIPPOCRATES, "that the children of women who menstruate during pregnancy cannot be healthy," appears partly true. The discharge probably proceeds from the vessels of the cervix uteri and vagina, in consequence of the more than usual vascular determination to the uterine organs during pregnancy, the periodic recurrence being the consequence either of ovarian excitement and influence, or of habit.

12. *Treatment*, in most instances, is unnecessary, or nearly so. In one of the two cases which I have alluded to, the lady who was its subject had four children, and this discharge occurred during each pregnancy. Nothing beyond the recumbent posture, and quietude as long as the discharge continued, was prescribed. Three of the four children are living and well, but are of delicate constitutions. HIPPOCRATES advises cupping over the mammae, and MAURICEAU bleeding from the arm. Neither of the cases which I saw required any depletion.

13. V. *WATERY DISCHARGES FROM THE VAGINA* have caused some discussion as to their source or sources. The fluid has been referred to the glands of the cervix uteri, but they cannot be supposed capable of furnishing so abundant and so clear a fluid; although these glands and those of the vagina often furnish a copious mucous secretion. The fluid is more probably collected between the amnion and chorion, or between the chorion and decidua, and evacuated during the advanced stage of pregnancy, or some time before the commencement of labour. In rare instances, the fluid may be actually the liquor amnii. Dr. BURNS remarks, that he has known cases where a considerable discharge of water has taken place after fright or exertion, with subsidence of the abdominal tumour, a feeling of slackness, and irregular pains, and yet the woman has gone to the full time. Other writers have made the same observation. Dr. DAVIS mentions these discharges, especially when they occur "in dribbling quantities weeks and months before labour," as indicative of great consequent danger. But in this other authors do not quite agree with him. The source of the fluid can be inferred only from the quantity and the recurrence of the discharge, and the effect produced upon the

abdominal tumour. If the discharge be great, sudden, and affecting the tumour, it may be referred to the escape of the liquor amnii. If it be gradual, small in quantity, and does not affect the abdominal tumour, it may proceed from the other sources pointed out.

14. The *treatment* consists in keeping the patient dry, clean, and perfectly quiet. An anodyne may be given as circumstances may suggest a recourse to it, and the bowels kept gently open by cooling aperients. Injections *per vaginam*, similar to those advised for *leucorrhœa*, have been recommended, but they are of doubtful efficacy; all perturbations, whether mental, physical, or medical, being much more injurious than beneficial.

15. vi. *DROPSY OF THE AMNION*.—See art. DROPSY, § 113, *et seq.*

16. vii. *RHEUMATISM AND SPASM OF THE UTERUS* have been described chiefly by German and French pathologists. Rheumatism may attack the uterus, as well as other fibrous structures, although much less frequently than those of more superficial or external parts. It is characterized by severe pain, increased on motion and the contraction of the abdominal muscles; by augmented sensibility and tenderness; and by symptomatic fever and restlessness.—*a.* It is caused by cold, currents of cold air, and the usual causes of rheumatism acting upon a rheumatic diathesis. VELTEN states that it was observed during an epidemic of rheumatism; and WIGAND, JOERG, and others, that it was caused by the projection of the clothes, during advanced pregnancy, by the enlarged abdomen, producing exposure of the lower part of the body. It may occur at any period of gestation, but is much more frequent in the latter months. The slighter states of it are very probably, as Dr. CHURCHILL suggests, what have commonly been called "false pains."

17. *b. Symptoms*.—The milder attacks consist chiefly of shooting pains in the region of the uterus, occurring at intervals, and either limited to a small space, or affecting the organ more generally. The severer attacks occur often suddenly, and without any apparent cause; are attended by violent pain in the region of the uterus, the duration and the character of the suffering distinguishing them from the commencement of labour, even although there may be distinct contractions of the uterus, and slight dilatation of the os uteri. In the milder forms there is little or no constitutional disturbance; but the more severe are attended by quickened pulse, hot skin, sleeplessness, and restlessness. Rheumatism of the uterus is generally accompanied with spasm, or irregular contraction of the organ, which is sometimes extended to the lower limbs. The irritation is occasionally, also, propagated to the bladder, causing frequent and painful micturition, and to the bowels, occasioning colic, tenesmus, or diarrhœa. "The motions of the child are a source of great torment, owing to the increased sensibility of the womb; and from some sympathy with the mother, it not infrequently happens that these motions are peculiarly lively."

18. When the affection occurs during parturition, WIGAND, DEZEIMERIS, and CHURCHILL state that the natural pains are arrested, or become tedious, ineffective, sudden or interrupted, and more distressing than usual. The pa-

tient is hot, thirsty, and irritable or restless; the pulse being quick, and either full, soft, and undulating, or small and hard. The uterus is very tender, the weight of the bedclothes occasioning much pain; and the cervix and os uteri are often tender and painful on examination. If the case be left to itself, the pains become weaker, or suspended for hours. If the patient falls into perspiration and sleep, the natural pains recur, and delivery is favourably terminated.—(CHURCHILL.)

19. *c.* The *diagnosis* between rheumatism and inflammation of the uterus consists in the more limited and continued pain of inflammation, and in the more sudden, spasmodic, and paroxysmal character of the pain of rheumatism. It is not improbable that some cases, occurring in the eighth or ninth months of pregnancy, are merely spasmodic paroxysms, or irregular contractions of the body of the organ, and not truly rheumatism affecting its structure.

20. *d.* The *prognosis* is generally favourable, when the patient comes early under treatment; but if she be neglected, abortion or premature labour may follow the continuance of the attack, and the repeated contractions of the uterus and spasm attending the complaint. Slight dilatation of the os uteri usually attends the period of severe suffering; but this part regains its natural state upon the subsidence of the attack. JOERG states that the child is less frequently injured by rheumatism than by inflammation of the uterus.

21. *e.* The *treatment* consists of venesection varying in amount from six to twelve or sixteen ounces, when the patient is young, strong or plethoric, and when there is fever with a hard or full pulse; of sedatives and diaphoretics; and of anodyne enemata. Opium with ipecacuanha may be given at bedtime, or DOVER'S powder; and, after opening the bowels by a suitable aperient, an emollient and anodyne clyster should be administered. An opium or belladonna plaster may be applied over the abdomen or loins; and diaphoretics should be administered at intervals, conjoined with an opiate or some other narcotic. The warm embrocation containing spirits of turpentine, with a considerable proportion of the wine or tincture of opium, may be applied over the abdomen. If the attack occur at the commencement of parturition, this embrocation, without the opium, will generally prove efficacious. The bowels ought to be kept quietly open, so as to prevent fecal accumulations; and the diet duly regulated.

22. viii. INFLAMMATION OF THE PREGNANT UTERUS.—Inflammations of the womb in the unimpregnated state, and after delivery, are described in the articles UTERUS and PUERPERAL DISEASES. I have merely to notice such peculiarities as hysteritis presents during gestation. As may be anticipated from the physiological conditions of the uterus, inflammation attacks the impregnated organ more frequently than the unimpregnated, although less so than after delivery.—*a.* It is *caused* by exposures to cold, by injury, by concussions of the trunk, by the abuse of spirituous liquors, and by the extension of inflammation from adjoining parts. Hysteritis during pregnancy and after delivery, as observed in the metropolis, is chiefly caused by the abuse of spirituous liquors, more espe-

cially of gin. It is said to be most frequently observed in the sanguine and irritable temperaments, and scrofulous diathesis, and seldom to occupy the entire uterus, unless in the very early months. In the latter months of pregnancy, it is more limited, affecting chiefly the lower portions or cervix. At earlier periods it is commonly seated in that part to which the placenta is attached. The inflammation is seated in the muscular structure, but the peritoneal coat may also be implicated; in which case partial or limited adhesions may form between the fundus or body of the uterus and adjoining parts, as I have observed in several instances.

23. *b.* The *symptoms* are a severe, constant, or aching pain in some part of the abdominal tumour, increased upon pressure, upon sudden motion, walking or descending stairs quickly, and by the movements of the child. It often extends to the back and groins. Sometimes dysuria, or a frequent desire to pass urine, or tenesmus, or pain on going to stool, is complained of. More or less sympathetic disturbance is produced, especially heat of skin, quickened pulse, thirst, nausea, or vomiting. "If the disease be very limited, the child may escape injury, and gestation be completed; but if more extended, the fœtus will probably perish in utero, or be prematurely expelled." Unless the disease be completely removed, and the womb restored to a healthy condition, the consequences during parturition may be very serious. Dr. GASON informed Dr. CHURCHILL that, in three cases of inflammation of the womb during pregnancy, rupture took place during labour in the exact spot previously diseased. Dr. E. MURPHY states that most instances of rupture of the uterus may be traced to lesions either previously existing or produced by inflammation. The wife of a respectable tradesman, for whose family I was often consulted, complained of hysteritis at an advanced period of pregnancy. She had had several children, and her constitution was much injured by gin-drinking. She sunk almost instantly upon delivery from sudden and profuse flooding. Inspection of the body was not allowed.

24. *c.* Hysteritis during pregnancy may *terminate*, 1st. In resolution, the patient going her full time and being safely delivered; 2d. In effusion of lymph and the firm adhesion of the placenta to the uterus; 3d. In softening of the structure of the organ, favouring rupture or dangerous or fatal hemorrhage; 4th. In the production of an abscess or small abscesses in the inflamed portion of the uterine parietes; and, 5th. Even in gangrene, as described chiefly by the German writers on diseases of the uterus.

25. *d.* The *prognosis*, as shown by these terminations, ought to be guarded, especially when the disease occurs in females addicted to the use of spirits, to whom it is frequently fatal in one of the ways now indicated.

26. *e.* The *treatment* should depend upon the habit of body, strength, and habits of the patient, and upon the extent and severity of the local symptoms and of the constitutional affection. Although the local suffering is generally less severe than in rheumatism of the womb, the constitutional disturbance is greater, and a more decided and prompt treatment is often required. In other respects the treatment is much the same as recommended for rheuma-

tism of the organ. Local vascular depletions are generally beneficial; and calomel, camphor, and opium are also of service. In other respects the treatment should be the same as advised for inflammation of the womb in the other articles comprising it. (*See* UTERUS and PUERPERAL FEVERS.)

27. III. AFFECTIONS OCCURRING SYMPATHETICALLY DURING PREGNANCY.—The general systems and the more remote organs may experience more or less disorder in the course of pregnancy, arising either directly from the altered state of the uterus; or indirectly, as from fecal accumulations in the large bowels, that are apt to form during the earlier periods of gestation.—i. THE DIGESTIVE ORGANS often experience more or less disorder. The slighter or less important of them may be only mentioned.—A. TOOTHACHE is frequently complained of, but is owing to the common causes of the affection; for it is not usually felt when these causes have not existed before conception; pregnancy, either directly or indirectly, aggravating merely a pre-existing evil. The bowels generally require moderate but repeated doses of stomachic aperients, and afterward anodynes, locally and internally, preparations of iron, narcotics, and antispasmodics, &c. The question as to the propriety of extraction, or of other painful operations for this complaint during pregnancy, may be considered as set at rest by having recourse to ether or chloroform inhalation.

28. B. SALIVATION is sometimes troublesome; but it is rarely of great importance. It will generally be moderated or removed by a judicious use of stomachic or cooling aperients, by cooling and astringent gargles, and attention to the states of the gums and teeth. Rinsing the mouth often with tar-water, or with mucilaginous fluids containing creasote or spirits of turpentine, will generally be useful, and also benefit the teeth and gums. *Capricious or morbid appetite* is not infrequent during pregnancy; but this topic suggests nothing of any importance in addition to what I have stated in the article APPETITE. If, however, carried to an extreme, it may, as well as frights and violent mental perturbations, affect the development of the fœtus.

29. C. NAUSEA AND VOMITING generally occur at some period of gestation—most frequently from the third to the sixth week after conception, although occasionally only a few days after this act; and sometimes not until the seventh or eighth month of gestation. At the earlier periods these symptoms are merely sympathetic. In the latter months they may, in some measure, be caused by the pressure of the uterus.—a. The patient usually finds her stomach uncomfortable on rising in the morning, and the discomfort soon amounts to nausea or vomiting. Whether the stomach be evacuated or not, the nausea ceases after a few minutes or within an hour; and, after some delay, breakfast is taken with the usual or good appetite, and without subsequent inconvenience. These attacks are renewed every morning for six weeks or two months, when they gradually subside. In some cases, vomiting does not occur until a full meal is taken. It may also take place at any time of the day, or in the evening. Instead of gradually ceasing about the third or fourth month, or after quickening,

it occasionally continues during pregnancy, causing great distress and some risk. If carried beyond certain limits, it may occasion miscarriage. When vomiting follows a meal the constitution of the patient languishes from a want of due nourishment as well as from the continued irritation, the patient even sinking from inanition or exhaustion. Several instances of this issue are recorded in the works referred to in the *bibliography*. When the progress of pregnancy is arrested by the death of the fœtus, then the vomiting ceases spontaneously. Instances have occurred of an internal organ, the uterus, stomach, &c., having been ruptured by the violence of the vomiting. The matters thrown off the stomach may be thin, watery, glairy, colourless; or consist partly of bile, or of blood. In severe cases they are greenish or blackish, owing to an admixture of bile or an exudation of blood. The vomiting is generally attended by tenderness at the epigastrium, prostration of strength, a weak, small, quick pulse, constipated bowels, and sometimes a loaded tongue.

30. b. *The causes* of the serious cases of vomiting during pregnancy have not been duly investigated even by those physicians who believe themselves the sole depositories of the knowledge of female maladies. Writers on these maladies have not even shown whether or not this vomiting may not result from disease of the uterus or of the ovum; and they have not always attended to the existence of disease of the liver and biliary apparatus, or of the duodenum and pancreas, or of the stomach itself; or to the presence of scybala, or of irritating substances locked up in the cells of the colon. They even furnish no information as to the states of the kidneys or of the ovaria—so little has a division of labour hitherto tended to advance this department of medical science. Cases, however, have occurred when dangerous or fatal vomiting has been caused chiefly by lesions seated as just stated, or by retained irritating matters, pregnancy merely developing and perpetuating a sympathetic disease, which in most of its morbid relations had previously existed, but had been latent, until it became aggravated or excited by the change in the uterine organs.

31. c. *The diagnosis* of vomiting should not be overlooked, with reference to its dependence or non-dependence on pregnancy. The chief circumstances indicative of its dependence on this cause are its occurrence and daily recurrence in connexion with the disappearance of the catamenia, the speedy return of appetite and of the appearance of good health in the intervals, the changes apparent in the nipple, areolæ, and in the mammæ, and the absence of any sign of disease of the stomach itself, or of any other organ.

32. d. *Treatment*.—In slight cases, and especially during the early months, little or no treatment is necessary: time will remove the disorder. But the bowels should always be kept gently open, as any accumulation in the large bowels aggravates the complaint. If nausea be distressing, and unaccompanied with vomiting, an ipecacuanha emetic will often be of use at an early period of gestation; and, after having evacuated the bowels, the infusion of calumba or of cheyreita may be given. If the patient

be very robust or plethoric, a moderate bleeding will be serviceable at the commencement; but at a later period, or when she is reduced by the duration of the disorder, it is inappropriate. Gentle stomachic or cooling aperients, suited to the circumstances of the case, are generally beneficial. The most useful are, the confection of senna with magnesia, [lemon-juice], the infusions of calumba and of senna with tartrate of potash, with an aromatic spirit; the compound infusion of roses with sulphate of magnesia, a little dilute sulphuric acid, and tincture of orange-peel; and, if the bowels are not much confined and the sickness more urgent, from a scruple to half a drachm of sulphate of magnesia with fifteen grains or a scruple of magnesia, and four or five drops of tincture of opium, in spear-mint water, taken once, twice, or thrice daily. In several cases, the nausea or the vomiting is aggravated or perpetuated by acidity, especially if flatulency is complained of. The infusion of calumba, with magnesia and ammonia, is then very beneficial. Small morsels of ice are sometimes of use.

33. In more severe cases, the application of embrocations over the stomach, or mustard poultices, or terebinthinate epithems, or blisters may be resorted to. When the matters thrown-off are acid, acrid, or attended by flatulent eructations, powdered charcoal, magnesia, ammonia, or other alkalies are severally of use. The hydrocyanic acid may also be given; or creasote, either in pills or in mucilaginous mixtures. The several preparations of opium or of morphia, conjoined with other medicines—either those already enumerated, or warm aromatics and spices, as capsicum, aromatic confection, &c.—are sometimes of service; and embrocations or epithems with laudanum over the stomach afford relief in the more urgent circumstances of the case. During the use of these means, the bowels ought to be preserved in an open state, either by such aperients as are most likely to be retained on the stomach, or by laxative and anodyne clysters. When the bowels are sufficiently evacuated, starch enemata, containing sirup of poppies or the compound tincture of camphor, will then be of service. In all circumstances the horizontal posture ought to be adopted, and strict attention paid to diet, the patient's desire for articles of food being indulged, if there be no reason to the contrary. When all other means fail, and the case admits of the measure, the induction of premature labour may be contemplated, or even attempted.\*

34. *D. HEARTBURN, PYROSIS, SPASMODIC AND COLICKY PAINS* are often complained of during pregnancy, and are severally relieved by antacids, conjoined with tonics, antispasmodics, and anodynes, and by a due promotion of the intestinal secretions and excretions, as just advised for *nausea* or *vomiting*, or as they are more fully directed in the articles *INDIGESTION, COLIC, PYROSIS, AND STOMACH*.

35. *E. CONSTIPATION OF THE BOWELS* is very common during pregnancy, and always aggravates the disorders of the stomach, which have been noticed above.—*a.* It is *caused* in some instances by the pressure of the gravid uterus

on the rectum and sigmoid flexure of the colon; by impaired action of the bowels in others, owing to vital and vascular determination to the uterus; and not infrequently it is increased by the impaction of hardened feces in the cells of the colon. Fæcal accumulations in the cells may exist, and may even endure for weeks or months without the constipation being remarkable; and in this way many of the disorders of pregnancy may be produced or aggravated; not merely those already mentioned, but also headaches, restlessness, watchfulness, colicky pains in the abdomen; weight, flatulence, and distention in this cavity; hemorrhoids, and sometimes diarrhœa or tenesmus. If these ailments continue or increase, owing to the retention of fæcal collections, inflammation of the bowels or dysentery, or abortion may supervene. If constipation, and the collections of fæcal matters in the bowels consequent upon it take place during the latter months of gestation, or be retained until the period of delivery, the diseases incidental to that period are very readily produced.

36. *b.* The *treatment* consists of the occasional recourse to the aperients already mentioned; to rhubarb and magnesia; to the infusions of gentian and senna, with such adjuncts as may suggest themselves; to confection of senna with sulphur and magnesia; to castor oil or olive oil taken in small and frequent doses: to the compound rhubarb pill, with extract of henbane and Castile soap, and sometimes, also, a little ipecacuanha; to emollient and laxative enemata; or to soap or oleaginous clysters. In obstinate cases more active means may be employed, with due reference to the situation of the patient; and for these I must refer the reader to the article *CONSTIPATION AND COSTIVENESS*.

37. *F. DIARRHŒA* is often met with during pregnancy as a consequence of improper food, &c., and of neglect of the bowels, or of constipation. It may be kept up by the presence of hardened feces in the cells of the colon.—*a.* It may occur at any period of pregnancy, and may arise from cold, from mental perturbation, from the state of the secretions and excretions, and without any assignable cause. The acidity consequent upon imperfect digestion often occasions it. Very recently I was consulted respecting a case which resisted absorbents, astringents, tonics, opiates, &c. The patient accidentally mentioned her addiction to the use of immoderate quantities of sugar. This substance was interdicted, unless in small quantity; and within three or four days afterward the same medicines as were previously taken without benefit removed the complaint.

38. *b.* The *treatment* consists of small doses of hydrarg. cum creta with DOVER's powder; or of small quantities of rhubarb with ipecacuanha and dried sub-carbonate of soda; of ipecacuanha with the extract of hop, or with the compound soap pill; of cretaceous mixture with compound tincture of camphor, or tincture of hop; and of flannel clothing worn next the skin, and suitable diet. (*See, also, art. DIARRHŒA.*)

39. *G. JAUNDICE* is not of frequent occurrence during pregnancy. It may appear at any period of gestation, but more frequently during the latter months, and in females who have had

\* We have known two cases where it was necessary to resort to this measure, and where it proved successful, saving, beyond doubt, the life of the patient.]

several children, or are advancing in life. It generally continues until after delivery. It may be caused by the pressure of the gravid uterus, but more frequently by some one of the several pathological conditions assigned in the article JAUNDICE. The symptoms vary with these conditions; and the treatment should have strict reference to them, as well as to the stage of pregnancy and other peculiarities of the case. Although laxatives, or even chologogue purgatives, may be cautiously employed and repeated more or less frequently, yet active cathartic or other heroic measures should not be prescribed. If nausea or vomiting occur, or diarrhœa, the remedies advised above for these may be employed; and the more urgent symptoms, as pain and spasm, should be palliated by means of narcotics, &c. If the symptoms indicate active congestion or inflammation of the liver, bleeding and other antiphlogistic means must be adopted.

40. ii. VARIOUS DISORDERS OF THE HEART AND RESPIRATORY ORGANS sometimes occur during pregnancy. These are apt to appear in hysterical or nervous females, and during a first pregnancy.—A. FAINTNESS, FAINTING, or full syncope, is most apt to occur at the period of quickening, but it may take place at any period, or may recur occasionally or frequently. Delicate and weak females are most liable to it. "Towards the end of pregnancy, fainting is regarded with much suspicion, not so much for the immediate consequences as for its effect upon convalescence after parturition." (CHURCHILL.) It may prove a serious affection if it depend upon passive dilatation of any of the cavities or orifices, or other organic disease of the heart: lesions which consultation will detect.

41. B. PALPITATIONS OF THE HEART are often connected with faintness or syncope, either of these preceding or following the other; and both affections often depending upon the pressure of the gravid uterus upon the digestive organs, and of these latter upon the diaphragm. The embarrassment thus occasioned to the circulation through the heart is often increased by collections of flatus in the stomach, and even in the œsophagus, as well as in other parts of the digestive canal, these collections being often retained by spasm of adjoining parts of the canal. These symptomatic affections are usually caused, developed, or aggravated by mental emotions and perturbations, by errors in diet, by startling noises or occurrences, by disordered states of the stomach and bowels, and by a susceptible and hysterical diathesis. The treatment is nearly the same for both affections. During the paroxysm of faintness the patient should assume the horizontal position; during that of palpitation, the sitting. Antispasmodics and stimulants are beneficial for both, especially those which are prescribed for HYSTERIA. Between the attacks, tonics, restoratives, quinine or cinchona, the bitter infusions or decoctions, stomachic aperients, with due attention to diet and regimen, will generally prevent a return of disorder.

42. C. COUGH AND DYSPNŒA may occur in the early months from sympathy. Either of these may then assume an hysterical character, the cough depending chiefly on sympathetic irritation of the larynx or trachea, and dyspnœa

arising either from the same cause or from affection of the bronchi or respiratory nerves. In these circumstances, both cough and dyspnœa are nervous, spasmodic, or hysterical. But in the advanced stage of gestation, both affections may be caused and continued by the pressure of the gravid uterus, and aggravated by flatulence, indigestion, and costiveness. The diagnosis should, however, be established by means of the stethoscope and percussion, and by an attentive consideration of the several rational symptoms, lest these symptoms proceed from pneumonia, bronchitis, tubercular disease, or some other malady that has supervened or been developed in the course of pregnancy. When these affections are merely nervous and sympathetic, the treatment should be antispasmodic and anodyne. The bowels ought to be freely evacuated, and kept duly open; and acidity of stomach and flatulence prevented by means of tonics, antacids, and carminatives, as already advised, the diet and regimen being duly regulated. If these affections occur in full and robust females, they may be connected with pulmonary congestion, and then blood-letting is requisite. When the cough is severe, the use of narcotics and anodynes is of service, in order to moderate it and to diminish the risk to the fœtus. If it be attended by dyspnœa, pain, or fever, or by adhesive or glairy expectoration, blood-letting is also proper, with antimonial and other diaphoretics.

43. D. HÆMOPTYSIS may occur with or without either or both of the affections just noticed. It is not often observed, for pregnancy more frequently removes than induces this complaint. When, therefore, it is met with during pregnancy, it should be viewed as a most serious evil, and the means advised for hemorrhages promptly employed, according to the state of the case, especially blood-letting, cupping over the back or thorax, acetate of lead with opium, digitalis, acids, antimonial diaphoretics, turpentine epithems applied over the chest, &c.

44. iii. DISORDERS OF THE NERVOUS SYSTEM DURING PREGNANCY.—A. HEADACHES are frequently experienced during utero-gestation; and chiefly by two classes of constitution: 1st, by the delicate, nervous, hysterical, and those deficient in blood; 2d, by the plethoric and robust. In the earlier months the nervous character of headache is most pronounced, in the later months the congestive or plethoric. This latter form is often connected with impeded circulation through the heart and lungs, in consequence of the pressure of the gravid uterus, and in this case more particularly it is aggravated by indigestion, flatulency, and costiveness. The nervous form of headache is often limited, as to the vertex—the *clavus hystericus*—or to one side—*hemicrania*. It is oftener felt in paroxysms than without intermissions; and it is unattended by flushings of the face, heat of scalp, or injection of the conjunctivæ. Congestive or plethoric headache is attended by flushing, increased heat of scalp, injected eyes, a sense of throbbing, distention or fullness, by intolerance of light and sound, and it usually commences in the forehead, and extends equally to both sides; it is also continued and sometimes increased by a meal; while the nervous variety is relieved by a meal and by stimuli.

45. The *treatment* is different in either case. The *nervous form* requires stimulants, antispasmodics, and tonics; as ammonia, camphor, valerian, cascarrilla, &c.; the *congestive*, moderate blood-letting, general, or local, according to circumstances, purgatives, diaphoretics, &c. In all cases, the diet and regimen ought to be suited to the form of headache which is complained of, and the uses of all stimulating or restorative beverages either allowed or disallowed accordingly.

46. *B. SLEEPLESSNESS* is sometimes a distressing complaint of nervous, hysterical, and delicate females, especially as pregnancy advances. It is most liable to affect those who shut themselves in-doors, and deprive themselves of exercise in the open air, and who sleep in too warm and ill-ventilated chambers, or with too much bed-clothes. It is often attended by restlessness, by anxiety respecting trifling matters, and ultimately by despondency, and even by hypochondriasis. It is also intimately allied, and often associated with, *nervous headaches*. It is much more rarely associated with plethoric headache.

47. *Treatment*.—Besides the means already advised for *nervous* and hysterical headaches (§ 45), I have seen decided benefit result from a draught at bedtime, containing a drachm of the tincture of hop, with five or six of the carbonate of ammonia, or from twelve to twenty grains of the carbonate of potash, or soda, or magnesia. When the sleeplessness is attended by indications of *plethora* and active determination of blood to the head, and with the usual indications of *congestive* headache (§ 44), then vascular depletions, purgatives, and other antiphlogistic means, and low diet, are required.

48. *C. DESPONDENCY AND HYPOCHONDRIASIS* are not infrequent in hysterical females, especially during a first pregnancy, and more especially in unmarried females. In married females, these moral affections are most commonly seen in the delicate constitution and hysterical diathesis, and are often attributable to no other exciting cause than the contemplation of the future pains and contingencies of child-birth, or the private contrarieties and anxieties of married life. In the unmarried, numerous and painful reflections serve to develop these mental conditions, and even to carry them on to a state verging on insanity, and subversive of due control. In many such cases, the sentiments and emotions excite the cerebral circulation, and this in its turn augments the despondency, or carries it beyond the limits of sane judgment and conduct.

49. The *treatment* depends upon the peculiar circumstances, moral and physical, of each case. If the despondency proceed from fears of the dangers of child-birth—a cause which seldom exists alone—a true statement of the small amount of that risk will generally allay such fears; for there are very few females, however inexperienced, who indulge such fears after knowing the truth, especially when their hopes are excited and promoted by affection. If the disorder of the mind is truly nervous or hysterical, agreeable society, change of scene and of air, gentle exercise, mental occupation of a pleasant kind, healthy air, and restorative treatment will generally remove it. If the temperature of the scalp, the appearance of the eyes

and countenance, and the action of the earotids, indicate increased determination of blood to the head, then moderate bleeding, especially if the patient be strong or plethoric, cold sponging the head frequently, mild purgatives, derivatives, warm clothing on the lower parts of the body, and light, digestible food, will be requisite, with such other means as the peculiarities of the case may suggest.

50. *D. CONVULSIONS* during pregnancy assume one or other of these forms—the *hysterical*, the *epileptic*, or the *apoplectic*. The first of these is confined to utero-gestation, and is much more frequent during the early months than at an advanced stage. It is chiefly dependent upon the vital excitement and vascular determination to the sexual organs, and affects chiefly the weak, delicate, and hysterical constitution. The character and treatment are in all respects the same as described in the article *HYSTERIA*. *Epileptic convulsions* are the most frequent forms of convulsions at an advanced period of pregnancy, and the *apoplectic* during or after parturition. They are fully discussed in the articles *CONVULSION* (§ 27–88) and *EPILEPSY*.

51. *E. PAINFUL AFFECTIONS OF THE MAMMÆ—Mastodynia*—often commence during pregnancy, with pricking or tingling sensations in them, followed by shooting pains, with slight soreness of the nipples and increased size of the mammæ themselves, and especially of the glandular structure. The pains may be either of a neuralgic character, and owing to sympathy with the increased excitement of the uterus, or altogether consequent upon the stretching of the fibrous envelope by increased development of the glandular structure. In the latter months the pain is often dependent upon active vascular determination, which may go on to inflammation and abscess.

52. The *treatment* consists of fomentations, or frictions with oleaginous and anodyne liniments, or emollient poultices. In many cases no treatment is necessary. In the severer attacks, if these means fail, anodynes, cooling aperients, and antimonial diaphoretics may be prescribed: blood-letting, general or local, is seldom required, unless great tension, enlargement, or increased heat exist, and then the application of a number of leeches, or even venesection, should not be delayed, especially in plethoric females, lest active determination and congestion should go on to inflammation and its usual consequence, abscess. (*See art. MAMMÆ.*)

53. *F. VARIOUS OTHER SYMPTOMATIC DISORDERS, AND EVEN STRUCTURAL DISEASES*, occasionally supervene in the course of pregnancy, owing either to the sympathy existing between the parts affected or to the pressure of the gravid uterus. To the former of these states anomalous affections of the organs of sense, especially of sight and hearing, altered sensibility of various parts, occasional spasms, slight attacks of singultus, eccentricities of conduct or of sentiment, &c., are chiefly owing. To the latter cause, hemorrhoids, incontinence, or retention of urine, varicose veins, cramps or spasms of the lower limbs, œdema, anasarca, ascites, &c., are chiefly to be referred, and are noticed in their relations to the pregnant state in the articles in which these several maladies are described.

54. III. INFLUENCE OF PREGNANCY UPON THE COURSE, TERMINATION, AND TREATMENT OF CHRONIC OR PRE-EXISTENT DISEASES.—A. Various pre-existent maladies have no influence in preventing conception; a very few have even the effect of favouring the act, especially tubercular and scrofulous diseases, when not very far advanced; glandular enlargements, slight hæmorrhages, hysteria, &c. Several of these maladies, indeed most of them, and especially those now named, are either altogether arrested in their progress, or impeded or rendered latent, owing to the vital determination to, and increased vascular action developed in, the sexual organs, and to the salutary influence exerted thereby throughout the economy. Pulmonary affections, especially tubercles in the lungs and hæmoptysis, are generally arrested, if not too far advanced; the pulmonary symptoms often almost disappearing during the continuance of pregnancy; but, soon after parturition, they often re-appear with much greater severity, and sometimes with various associations. When pregnancy occurs at an advanced stage of phthisis, the disease is only partially abated, or rendered somewhat more latent; and in this case, not only is the child born with tubercles already formed, as I have ascertained by inspection in three instances, but the mother sinks in a short time after delivery, with remarkable increase of the pulmonary symptoms, either granular degeneration of the kidneys, with anasarca, ascites, &c., or delirium, or some other complication, besides the more common one of colliquative diarrhœa, rapidly appearing, and accelerating a fatal issue. When the pulmonary symptoms are only slight, the tubercles not having gone on to softening, then not only may pregnancy arrest the farther progress of the malady, but also may subsequent lactation, if duly managed so as not to impair the strength, exert a similar preservative influence, until pregnancy again recurs; and thus the disease, which had appeared before marriage, and had even been attended by hæmoptysis, be kept at bay for several pregnancies, or until the cessation of child-bearing, when it generally reappears and runs its usual course. I have seen a lady who had experienced an attack of hæmoptysis before marriage, have nine children, and enjoyed tolerably good health, and, having ceased to become pregnant, die of consumption two or three years after the birth of her last child.

55. Although pregnancy thus arrests the progress of chronic maladies in most instances, yet, if these maladies are of so severe a character as not to be removed altogether, as some of them are, by this state, and by the changes induced by it in the frame, they may be very remarkably aggravated after parturition, or during the last stage of gestation. Epileptic seizures may be rendered fewer or slighter during pregnancy, especially in the earlier periods; but they may be more severe at an advanced period, or even fatal during parturition. Paralytic affections, even hemiplegia or paraplegia, may be complete, and yet the patient become pregnant, bear a child at the usual period, and even become pregnant several times; but there is an increased risk of apoplectic seizures or convulsions during advanced pregnancy and during parturition. Pregnancy has generally a beneficial effect upon hysteria, leucorrhœa, and

dysmenorrhœa, but there are not infrequent exceptions; and in several other diseases so many circumstances tend to vary the results, provided pregnancy actually occur in their course, that nothing precise can be advanced respecting them. During chlorosis and anæmia, particularly the former, pregnancy may not take place; but if it occur in either, a very beneficial change generally results.

56. B. As to the management or treatment of pregnancy thus occurring during chronic maladies but little can be said. The suggestions of good sense, guided by pathological knowledge, will point out what ought to be done and what avoided, in the different and ever-varying circumstances in which medical advice will be required. In most instances, officious interference will be more prejudicial than beneficial; and the operations of nature, aided by suitable diet, pure, temperate, and dry air, and a gentle promotion of the several vital and excreting functions, will do more than any plan that can be laid down. Heroic or even active remedies should be avoided. They are out of place in these cases, and are only employed by charlatans and pretenders in and out of the pale of the profession. In these, as well as in other circumstances, it is not only the probable good which may be done, but the possible evil also which may follow, that should engage our minds and guide our determinations as to the use of any remedy and the adoption of a particular plan of cure.

57. IV. INFLUENCE EXERTED BY PREGNANCY ON THE PRODUCTION, COURSE, AND TREATMENT OF ACUTE MALADIES.—A. During pregnancy, the increased manifestations of vital action throughout the frame tend to ward off many of the slighter causes of disease, and even others of a more energetic kind, which would have, in other circumstances, been productive of disease, fail of causing it, or cause it in a less degree, during this state. Various epidemics have been observed to affect a smaller proportion of pregnant women than of others, and even endemic diseases have been less frequent among them. Epidemic diseases of a malignant character, or those which often assume a malignant form, as smallpox, scarlet fever, measles, erysipelas, typhous and adynamic fevers, are liable to become not only malignant, but rapidly fatal when they attack pregnant females, although this class of females are less predisposed to them than others. If these maladies appear at an early stage of gestation, abortion is likely to occur, and the danger is thereby increased; if they appear at an advanced period, or shortly before parturition, premature labour often takes place, and a fatal issue very frequently results soon after delivery. Other acute diseases, as inflammations of any of the viscera, although occurring less frequently in pregnant than in other females, are also attended by much increased risk, not only of abortion, but even of dissolution; although the danger is, upon the whole, not so great from these attacks as from exanthematous and malignant fevers. HIPPOCRATES (*Aphorism.*, L. v., 30) says, that "pregnant females seized with an acute disease never recover." This inference, however, is too general, for recoveries take place, in some instances, from most of the acute maladies which have been now enumerated, but

the danger is always great, even in cases of inflammation of the respiratory organs or pleura; and it is not less so, if not even greater, when inflammation of other important or vital organs takes place during pregnancy.

58. *B. The treatment of acute maladies attacking pregnant females should be appropriate to the nature of the disease, to the pathological conditions of the case, to the progress it has made, and to the circumstances of the patient and the stage of her pregnancy.* In most epidemic, or exanthematous, or febrile maladies which are not truly inflammatory, violent or perturbing remedies should be avoided; vascular depletions, the promotion of the abdominal and cutaneous excretions, and due support of the vital powers being severally prescribed, as the nature of the disease and the circumstances of the case may require. In every instance the malady should be carefully watched, remedies cautiously administered, and the various offices of the nurse assiduously performed. The numerous details which a due discussion of this subject might involve are beyond my limits. They will readily suggest themselves in practice to the observing physician, who will act in all things appropriately to the peculiar circumstances both of the disease and of the patient.

**BIBLIOG. AND REFER.**—Hippocrates, *Εντακτωρ*, Op., p. 600.—*Galen*, De Causis Symp., i. 7.—*Pliny*, Hist. Nat., xxiii., 56.—*Aetius*, xvi., 10.—*Paulus Aegineta*, l. i., c. 1.—*Sydenham Edit.*, p. 4. Mr. ADAMS has given references to several of the ancients, and has added the following directions, given by ASPASIA (apud *Aetium*, xvi., 12) for the management of pregnant females: "Women who have conceived are to be guarded from frights, sorrow, and all violent mental perturbation. They are to avoid gestation in carriages, severe exercise, inordinate breathing, and blows about the loins; also the lifting of heavy loads, dancing, and sitting on hard seats. Likewise all acrid and flatulent food and drink are to be avoided. All discharges of blood, from the nose or hemorrhoids, are dangerous in the pregnant state. Moderate and wholesome food, gestation in a sedan, gentle walking, soft friction, and the exercise of spinning are proper. About the eighth month, which is the most critical period, the diet is to be more contracted, and the exercise increased. If the bowels are constipated, owing to the compression of the rectum by the enlarged uterus, laxative food is to be given, such as pisan and malwols. In the ninth month the regimen is to be of a relaxing nature, and for this purpose the tepid bath is to be frequently taken, for it has great effect in rendering parturition easy."—*Avicenna*, Canon., l. iii., 21, 2, 2.—*Haly Abbas*, Pract., l. i., c. 19.—*Primeriosius*, De Morbis Mulierum, l. iv., c. 2.—*F. Meigs, M.D. Philad., 1848.]

**PROSTATE GLAND.—DISEASES OF.**—This gland is seldom diseased in young persons; but it is much more frequently affected after puberty, and with advancing age. It is very often diseased in old persons; and generally at this period of life its diseases are associated with those of the bladder, often also with those of the kidneys and urethra; and sometimes gravel or urinary calculi are superadded. The diseases of this gland are, 1st. Inflammatory; and, 2d. Organic or structural; certain of these latter being independent of inflammatory action, and frequently associated with other diseases of the urinary organs.

**INFLAMMATIONS OF THE PROSTATE GLAND.**—**SYNON.** PROSTATITIS; *Inflammation de la prostate*, *Prostatite*, Fr. *Entzündung der Vorstehdrüse*, Germ.

**CLASSIF.**—III. CLASS, I. ORDER. (*Author in Preface.*)

1. **DEFIN.**—*Pain and heat in the perinaeum extending to the anus; frequent micturition, with a scalding sensation on voiding urine; tenesmus; and sensible enlargement and heat of the gland upon examination per rectum, with symptomatic fever, and sometimes retention of urine.*

2. Inflammation of this gland may be either *acute* or *chronic*, and each may occur primarily; but the chronic is often consequent upon the acute, owing as frequently to the constitution and age of the patient, and the complications of the disease, as to any fault in the treatment. Either of these states of the disease may arise from causes common to both, and be followed by nearly the same, or the very same organic lesions. Prostatitis, whether acute or chronic, may be the *primary* malady, and occasion diseases of other associated parts; or it may be *secondary*, or consecutive of these diseases, or of urinary deposits or calculi.

3. i. **THE CAUSES OF PROSTATITIS** are chiefly premature or excessive excitement of the sex-

ual organs, especially manustupration; riding much on horseback or in a carriage; sitting habitually on warm cushions, or accidentally on wet or damp cushions; a frequent or habitual neglect of due evacuations of the urine or of the bowels; the abuse of such purgatives as irritate the rectum, as calomel, blue-pill, aloëtic preparations, &c.; frequent costiveness or constipation; dysenteric attacks; inflammations of the urethra, especially gonorrhœa, gleet, &c.; strictures of the urethra; the use of various substances recommended for the cure of gonorrhœa or glects, especially irritating or astringent injections, and stimulating gum-resins and balsams; nutritious and highly-seasoned viands; excessive use of spirituous and vinous liquors, or of strong coffee; aphrodisiac substances, especially cantharides taken internally or applied externally; exposure of the lower extremities to cold or wet, especially if the individual be of the gouty, gravelly, or rheumatic diathesis; catarrh or inflammation of the urinary bladder; morbid secretions from diseased kidneys; the irritation or pressure of calculi in the bladder; the irritation of worms in the rectum; and injuries sustained in or near the perinæum and anus. Either of these causes may develop the disease, especially during advancing age, and in persons who are addicted to venereal excesses.

4. ii. SYMPTOMS.—A. *Acute Prostatitis* is attended by increasing heat and pain in the perinæum that extend to the anus. Micturition is frequent, and accompanied with pain and scalding upon passing the urine, these sensations being increased "as the *accelerators urinae* contract to expel the last drops of urine." Mr. Coulson accurately observes, that evacuations from the bowels cause great uneasiness; and there often remains a sensation as if the rectum was not completely emptied, giving rise to distressing tenesmus. Upon making an examination *per rectum*, "the prostate is felt as a smooth, round, and hard body, projecting downward on the bowel," which feels hot; and pressure on the gland is exceedingly painful. If a catheter or sound be attempted to be introduced, it passes without difficulty as far as the membranous part of the urethra; but its passage onward is attended by acute pain and severe spasmodic contractions. The above symptoms are aggravated by sitting, standing, or riding on horseback or in a carriage, or by exercise or exertion of any kind, and by the use of heating or stimulating beverages.

5. When resolution takes place, the above symptoms subside; but if the inflammatory action continues unchecked, the inflammation extends to the neck of the bladder, or even farther, and, with the tumefaction of the gland, gives rise to *retention of urine*. In this case the febrile symptoms are remarkably exacerbated; and if retention be prolonged, delirium, followed by coma, owing to excrementitious plethora, may result, if the inflammation be not subdued or the bladder emptied.

6. When rigours occur, with increase of the febrile symptoms, quickened pulse, hot skin, and furred tongue, especially toward the evening; with a sense of fullness, tension, or throbbing in the perinæum; and with more frequent calls and increased difficulty of micturition, the existence of suppuration may be inferred. Mr.

Coulson states, that if the prostate be now examined through the rectum, it will no longer be found hard and resisting, but resembling a distended bladder. The examination, as well as the discharge of feces, causes great pain, and there is constant tenesmus with a sense of burning. The fibrous investment of the gland, softened by inflammation and distended by pus, sometimes exudes a creamy and sanguineous matter into the urethra, the rectum, or the bladder; and then the tumour subsides, the urethra becoming freer, the bladder emptying itself, and the symptoms abating. If the abscess opens into the urethra, the evacuation of urine is preceded or followed by a copious discharge of purulent matter by this passage. Mr. Coulson remarks, that in some cases more or less blood is mixed with the discharge, and that he has known a considerable hemorrhage to take place. After the last drops of urine are voided, there is a stinging pain which lasts for a few minutes, or for a longer period; and there is also a burning pain in the glans penis.

7. B. *Chronic inflammation of the prostate gland* is sometimes a consequence of the acute state of prostatitis, especially when the inflammatory action is only partially subdued and not entirely removed. It is occasionally, also, a reproduction of the morbid action in a milder and slower form, in consequence of the influence of one or more of the causes during or soon after the subsidence of the acute attack. The prolongation of the inflammation in a chronic form, after the acute symptoms are subdued, is often owing to the gouty or rheumatic, or scrofulous diathesis, to gravelly or calculous formations, to the use of stimulating beverages, and to venereal indulgences. Mr. Coulson remarks, that sometimes, in feeble subjects, the antiphlogistic treatment stops the progress of the inflammation at a period of the disease when pus has already formed in the prostate, but has not effected its discharge. Infiltrating the cellular tissue connecting the lobes of the gland and surrounding parts, or contained in small abscesses, this purulent matter becomes more consistent by the absorption of its more fluid parts, and gives rise to cheese-like or tubercular formations, which excite slight attacks of inflammation, with increased deposition and bulk of the gland.

8. More frequently, however, chronic prostatitis commences primarily, and the gland assumes an enlarged, and sometimes an indurated state, owing to the absorption of the more fluid portions of the serum and lymph deposited by inflammatory action into the cells of the connecting cellular tissue. Each exacerbation of the morbid action is thus followed by increased symptoms and size of the gland.

9. The symptoms of chronic prostatitis thus vary with the mode in which the disease commences and proceeds. In the *consecutive form* (§ 7) they are merely the protracted continuance of a milder state of the symptoms than existed during the acute stage, either after intermissions or without, or with remissions of varying duration. When chronic prostatitis is *primary*, it is often long neglected, owing to the gradual increase of the inconvenience, and to the symptoms being mistaken for those of internal piles, until difficulty of micturition suggests the origin of the evil. When the gland

becomes enlarged from the continuance of inflammatory irritation, the patient has a sense of weight and bearing down, and a desire to go to stool, although the rectum is empty. The urine is voided every hour, or oftener, although but little has collected, and so slowly that it drops or dribbles merely from the orifice of the urethra; slight pain being felt in the glans penis and course of the urethra. The symptoms are increased by riding, walking, or standing, and are attended by symptomatic pains in the loins or down the thighs. There are generally, also, constipation and dyspepsia; sometimes headache or scaly eruptions on the skin; and occasionally slight hemorrhage from the urethra. The increased size of the prostate always interferes more or less with the exercise of the functions of the urinary bladder. The inability to discharge readily the contents of the bladder, owing to the impediment produced by the increased size of the gland, and by the associated changes in or near the neck of the viscus, is the chief and the most serious effect of this disease. If, after exertions to empty the bladder, an ounce or two of urine are left in it, the desire to micturate quickly returns, and renewed efforts are made in vain to expel it. This distressing symptom is much increased by exposure to cold or wet, by irregularity of diet, by stimulating liquors, and by constipation of the bowels. Sometimes, instead of retention, there is incontinence of urine; or, during sleep, the urine passes involuntarily.

10. Chronic inflammation, or *enlargement* of the prostate, with or without *induration*, is generally a disease of middle life or aged persons; but has also been met with in the young, chiefly in those who have been addicted to self-pollution. In these, as well as in other circumstances, the mucous follicles increase in size, and the surrounding cellular tissue becomes thickened, the prostate being thereby considerably enlarged, and the desire and difficulty of passing urine proportionably augmented. When the gland becomes so far enlarged as to prevent the entire evacuation of the urine, the retained portion becomes ammoniacal; pain and numbness are felt in the *glans penis*; sense of weight or uneasiness in the perineum; pain in the back of one or both thighs, in the loins, and in the sciatic nerves; and the feces are flattened. In aged or middle-aged persons, the enlargement is often *complicated* with *hemorrhoids*, or *prolapsus ani*, and sometimes with both. The ammoniacal smell of the urine becomes more offensive as the disease advances; and the urine, occasionally, is white and milky, owing, in some measure, to the extension of inflammation to the internal surface of the bladder. If, however, the urine be retained, it presents the appearance of coffee, occasioned by the admixture of blood with it.

11. Sir B. BRODIE remarks that, with far-advanced age, "the prostate usually, perhaps invariably, becomes enlarged." This change takes place slowly and at first imperceptibly; and the term chronic enlargement is not improperly employed to distinguish it from the inflammatory attacks to which the prostate is liable in early life. It may in some respects be compared with the chronic enlargement of the thyroid gland, known by the name of bronchocele. Like the latter, it is generally slow in its progress, and

often, after having reached a certain point, it remains stationary for many years, if proper treatment be adopted. It rarely terminates in ulceration or in abscess.

12. Upon *dissection*, the prostate is found enlarged sometimes laterally, but most frequently in the middle or third lobe. Enlargement of the lateral lobes has existed to a very great extent without having occasioned retention of urine; but even moderate enlargement of the third or middle lobe may occasion retention; for, being situated immediately behind the orifice of the urethra, the urine behind the tumour formed by it presses it against the orifice, and it thus obstructs the passage. Sir B. BRODIE remarks, that the tumour of the third lobe varies in size from a horse-bean to an orange. When small, it is of a conical shape, with the apex projecting into the bladder, and the base continued into the gland; but when large, the base is often the narrowest part. In some instances there is another tumour also projecting into the bladder, formed by one of the lateral portions. The canal of the urethra where it passes through the enlarged prostate is generally flattened. Not infrequently the enlargement so alters the direction of the urethra, that, instead of pursuing a straight course through the gland, it is inclined first to one side and then to the other. The urethra is, in some cases, narrowed by the enlarged gland; but in others it is wider, and even dilated into a kind of sinus, where it lies in the centre of the prostate.

13. iii. THE DIAGNOSIS of enlargement of the prostate is determined by examination per rectum and by the introduction of a bougie or catheter into the urethra. The former mode, however, although it will furnish evidence of the existence of enlargement, may not determine the presence of enlargement of the middle lobe. The introduction of the catheter will, however, soon settle the question as to disease of this lobe. The symptoms of retention of urine from enlarged prostate are not very different from those caused by stricture, but Sir B. BRODIE remarks that the terminations are different. He has never seen a case in which the bladder has given way in the former, as sometimes happens in the latter state of retention.

14. iv. THE PROGNOSIS—A. Of *acute Prostatitis* depends upon the progress of the disease, and the age and other circumstances of the patient. At an early stage of the disease, and before the symptoms of suppuration have appeared, if the health of the patient be not otherwise bad, a favourable prognosis may be given; but in the aged, in a constitution exhausted by excesses, and especially if symptoms of abscess be present, a guarded or an unfavourable opinion should be entertained of the result. When the pain is throbbing, is attended by shivering, and the disease has passed eight days either unsubsided by treatment or neglected, then suppuration has generally commenced, and probably advanced through the connecting cellular tissue; and in this case the patient often ultimately sinks, either one or several abscesses being formed, which may open into the urethra, or into the rectum, or through the fascia, cellular tissue, and perineum. But the abscesses may burrow and form fistulous passages, and cause wasting suppuration. An unfavourable

issue may occur before the abscess makes for itself an exit, owing to the retention of urine produced by it, and to consequent excrementitious plethora, causing fatal coma or apoplexy. This, however, will rarely occur when the patient receives medical aid. If the abscess opens into the urethra or rectum, the infiltration of excrementitious fluids through the orifice will rapidly aggravate the symptoms and accelerate the result. When the matter is early evacuated per perinæum, recovery may be expected, if other circumstances be favourable or the disease be uncomplicated, no serious disease of the kidneys or bladder being associated with it.

15. *B. The Prognosis of Chronic inflammation and enlargement of the prostate gland* is always unfavourable. When the patient is not very far advanced in age, and the constitution is otherwise not materially impaired, then the enlargement and hardening may sometimes be reduced, especially when the disease has not been of very long duration. But in advanced age, in weakened constitutions, and when the disease is associated with inflammation or structural lesions of the bladder or of the kidneys, little hope of recovery can be entertained, although life may be prolonged for a considerable time, if the complication be not of a very severe and dangerous nature, by careful treatment and regimen. Mr. COULSON observes, that "tumefactions of the prostate which are brought on by strictures, disappear when these are cured; it is necessary, therefore, to distinguish them from more permanent disease."

16. *v. COMPLICATIONS.*—Acute as well as chronic prostatitis, with more or less enlargement of the gland, is not infrequently associated with one or other of the following affections: with the gravelly, especially the phosphatic diathesis; with calculous concretions in the bladder or kidneys; with irritable, inflammatory, and thickened states of the bladder; with hemorrhoids or prolapsus ani; with gonorrhœa or gleet; or with stricture of the urethra. In the more chronic states of inflammatory action of this gland, and especially when the enlargement and induration are considerable, one or other, or even more than one of these complications, is often observed.

17. *vi. TREATMENT.*—*A.* In *acute prostatitis*, before symptoms of suppuration appear, the treatment should be strictly antiphlogistic, and consist of the application of leeches, or of cupping over the perinæum; of cooling diaphoretics, especially the liquor antimonii tartarizati, with liquor ammoniæ acetatis and spiritus ætheris nitrici, in camphor water; of DOVER'S powder at bedtime; of cooling saline aperients, and cooling lavement in the morning; and of farinaceous or vegetable diet. If there be much heat about the anus, a frequent injection of a cold fluid and cooling lotions to the perinæum and anus will be of use. And, in such cases more especially, the patient should recline on a horse-hair sofa, or sit upon an open cane-bottomed chair. The patient's beverages should be diluent and demulcent, and all stimulating and heating food and drink ought to be avoided. If retention of urine be threatened, owing to the swelling of the gland or of the middle lobe, and if cold enemata and cold lotions have failed, the hip-bath, demulcent and soothing clysters,

and fomentations or poultices to the perinæum may be resorted to. But, until these and the foregoing means fail, the introduction of instruments should not be attempted. When recourse to these is required, the able advice given by the surgical writers referred to in the *Bibliography* should be adopted.

18. *B.* If *suppuration* has commenced, Sir B. BRODIE and Mr. COULSON advise an early external discharge for the matter, in order to prevent it bursting into the urethra. The early and free puncture of the perinæum down to the gland, save where little or no matter has yet formed, is generally useful, by the loss of blood, and the removal of the tension of the parts. If the disease have anticipated the operator, and the abscess have opened into the rectum or urethra, then the general health should be maintained. If it have burst into the latter canal, then a flexible catheter ought to be retained in the bladder, and such other means as the peculiarities of the case may require, aided by surgical assistance, ought to be adopted.

19. *C. Chronic inflammation and enlargement of the prostate* require at first small but repeated local depletions from the perinæum; abstinence from venereal indulgences; rest in the horizontal posture, and sleeping on a hair mattress; a farinaceous and vegetable diet, with cooling and demulcent diluents, and a gently open state of the bowels, procured by means of cooling aperients, as the confection of senna with magnesia, or bi-tartrate of potash, or with sulphur. These means will be often of service, if persevered in for some time. If these fail, emollient injections, with henbane or sirup of poppies; or suppositories with henbane or hemlock; or the local applications of ointments containing the iodide of potassium, as advised by Mr. STAFFORD; and the internal administration of the iodide of potassium with liquor potassæ in camphor-water, or in mucilaginous or demulcent fluids, or with sarsaparilla; or the tincture of the sesquichloride of iron, taken in the infusion of calumba or of quassia, when the disease is associated with the phosphatic diathesis, or the hydrochlorate of ammonia in gradually increased doses, may severally prove of some service. Blisters and issues to the perinæum, mercurial ointments, camphorated and volatile liniments, anodyne, and narcotic suppositories, have likewise been recommended. The judicious employment of these may either prevent the accession of, or relieve, or even remove, retention of urine. But when these fail, recourse to surgical aid ought not to be delayed; and for opinions as to the employment of surgical means, I refer the reader to the works enumerated below.

## II. ORGANIC LESIONS OF THE PROSTATE GLAND. CLASSIF.—IV. CLASS, IV. ORDER. (See Preface.)

DEFIN.—*Changes of structure of the prostate gland, of various kinds, resulting generally from prolonged vascular excitement, or functional or nervous irritation, causing disorder of, or obstruction to, the urinary excretion, and often associated with other affections of the urinary organs and rectum.*

20. *i.* The most frequent ORGANIC LESIONS of this gland are ENLARGEMENT and INDURATION, consequent upon chronic inflammation.—*a.* But these changes may take place independently of any actual inflammatory action, frequent func-

tional excitement consequent upon entertaining prurient ideas, or upon frequently practiced self-pollutions or other venereal excesses, often occasioning these lesions independently, as well as in consequence of inflammatory action, either acute or chronic. There is every reason, moreover, to infer that sexual desires and frequent excitement of the genitals are attended by more or less active congestion of the prostate, with or without increased prostatic secretion, which, if continued habitually for a long period, will pass into enlargement and induration, and often occasion obstruction to the excretion of urine. M. VELPEAU notices, by the appellation of "*Catarrh of the prostate*," an increased flow of the prostatic secretion, arising from prolonged gonorrhœa or gleet, or frequent attacks of these, and appearing chiefly when the patient has been to stool or has passed his urine. Although sometimes supervening upon inflammatory states of the urethra, this morbidly increased secretion is more frequent after habitual self-pollutions and sexual excitement, and is attended by congestion or active determination of blood to the gland with more or less enlargement, and with several of the symptoms of prostatitis in a slight degree.

21. *b.* Swelling or enlargement of the gland from a varicose state of the vessels, mentioned by CHELUS, is merely a form of congestive or non-inflammatory enlargement. It generally occurs slowly in old persons, after venereal excesses, after repeated attacks of gonorrhœa or gleet, after hemorrhoidal complaints and constipated bowels, and after abuses of stimulating liquors. It is met with most commonly in the sedentary and those who live richly; the difficulty of emptying the bladder increasing, and becoming great, especially after violent exertion, and after heating food and drink. The swollen prostate is felt *per rectum*, but it is free from pain, and there is no pain in the passage of urine through the urethra. "The varicosity is situated rather in the coverings of the prostate. The substance of the gland itself is sometimes soft and spongy, sometimes tense and hard."

22. *c.* The treatment of these states of enlargement of the prostate depends much upon the evidence of their source. If they be consequent upon congestion or active determination to the organ, and if the constitution be not remarkably impaired, local depletions should be prescribed. Clysters of cold water, or of the decoction of oak-bark, with alum; attentive regulation of the bowels; and a cautious use of the catheter, with the other means suggested for the removal of the chronic states of prostatitis, are generally of service (§ 19).

23. *ii.* TUBERCULAR DEPOSITES IN THE PROSTATE, and small puriform collections disseminated through the gland, are mentioned by M. VELPEAU as having been, in rare instances, observed by him, and attended by more or less swelling. They may go on to ulceration or abscess, and terminate in fistulous communications with the urethra or rectum.—*a.* Dr. BAILEY has also observed *scrofulous disease* of this gland, as, upon dividing it, a white curdy matter has been found in it; and scrofulous pus has been forced out of its ducts. Mr. WILSON states that he has seen the prostate enlarged and changed into a white curdy matter, precisely the same in quality as that formed in a

scrofulous absorbent gland. Mr. GUTHRIE has met with a case in which the enlargement caused by scrofulous deposits or suppuration of the prostate was remarkably great. It is probable that these scrofulous changes are merely the results of sub-acute or chronic inflammation of the gland, occurring in scrofulous subjects, and giving rise to the formation of scrofulous pus, in the form either of small deposits or of larger collections, which become more or less altered by the absorption of their more watery parts, or by the occurrence of consecutive irritation and softening.

24. Mr. WILSON states that scrofulous swellings of the prostate are usually found in persons not advanced beyond the middle period of life; that they are slow in their progress, and not attended by much pain; that they may be felt *per anum*; and that their effects upon the excretion of urine depend upon the size and form they assume.

25. *b.* The treatment of scrofulous enlargements of the prostate consists chiefly in the use of the iodide of potassium with liquor potassæ and sarsaparilla; of sea-water, or of cold water with salt dissolved in it, topically, and occasionally as a clyster; of sea-bathing and sea-air; and of the application of an ointment of the iodide of potassium to the gland in the manner recommended and explained by Mr. STAFFORD.

26. *iii.* ULCERATION OF THE PROSTATE is sometimes observed.—*a.* It rarely occurs in the anal aspect or surface of the gland, unless as a consequence of the extension of ulceration, or of cancer of the rectum. It is not infrequently seen in the urethral surface of the gland, sometimes near the bladder, but oftener near to or on the *verumontanum* itself. Ulceration is a consequence generally of scrofulous disease of the prostate, or of purulent formations, or of injuries occasioned by bougies or catheters.

27. *b.* The diagnosis of ulceration of the prostate is very obscure. The appearance of blood on a bougie, or after micturition; the existence of pain in the situation of the gland, and the acute exacerbation of pain upon the passage of a bougie, and upon micturition, will suggest the probable existence of ulceration, but by no means prove it; inasmuch as these symptoms attend inflammation of either the prostate itself, or of the prostatic portion of the urethra.

28. *c.* The treatment which these symptoms suggest will depend upon, and vary with the circumstances of the case, but it will not be materially different from what has been recommended above for the consequences of *prostatitis* (§ 18, 19).

29. *iv.* HEMORRHAGE FROM THE PROSTATE may occur from ulceration, from the opening made by an abscess, from the accidental rupture of vessels, or from injury by a catheter. In these the hemorrhage is rarely very great, and the blood passes by the urethra; but when it is excessive, it may flow into the bladder, where its presence, especially its coagula, always occasions distress. In a case published by Mr. CORLAND HUTCHISON, the bladder was suddenly filled with blood, which proceeded from "two fungoid tumours which projected into this viscus from the prostate gland." The bladder was perfectly healthy. The entrance of the urethra was situated between the two tumours; the left being about the size of a hen's egg, and

the other that of a walnut. (*Lond. Med. Repos.*, vol. xxii., p. 130.) The treatment of hemorrhage from the prostate does not differ from that advised for hemorrhage from the urinary passages. (See art. HEMORRHAGE, § 215.)

30. v. FUNGO-ENCEPHALOID DISEASE AND CANCER have been met with in the prostate.—A. In the former, either the fungoid or the encephaloid structure may predominate. This form of malignant disease may be primary and solitary, as in an interesting case recorded by Mr. STAFFORD; or it may be a part only of a more general manifestation of this malady.

31. B. *Carcinoma*, or scirrhus-cancer, of this gland is rarely seen; but the prostate may be implicated in scirrhus, or cancer of the rectum. It is rare that scirrhus of the prostate occurs primarily, or in an uncomplicated form. Sir B. BRODIE, however, has adduced cases in which scirrhus appears to have affected this gland primarily.

32. C. When fungo-encephaloid malignant disease is seated in the prostate, there is not only great enlargement and retention of urine, but also an elastic or soft tumour felt *per anum*, sometimes with hemorrhage from the urethra, following efforts to pass urine. A scirrhus state of the gland is indicated by acute intermitting pains in the prostatic region, unconnected with the excretion of urine, and enlargement with a stony hardness of the prostate felt *per anum*, in addition to the usual symptoms of chronic enlargement.

33. vi. CALCULI IN THE PROSTATE.—The calculi found in the cavities of the prostate have been too generally viewed as quite different from those formed in the bladder, and as being altogether similar to those concretions sometimes found in the salivary ducts and elsewhere. It is not improbable that, while there are some which thus originate, there are others which are formed chiefly from urinary deposits; or which, originating in the gland itself, become greatly enlarged by urinary deposits, the prostatic calculi being only the nuclei around which these deposits are formed. It should be recollected that, when there is obstruction to the passage of urine through the urethra, owing to stricture, the prostate gland is then sometimes seen with its follicular cavities very much widened, and its ducts dilated; the latter being even as much enlarged as to admit of the introduction of a crow-quill. When, therefore, the urine is prevented from passing by stricture, or passes only in small quantity, some of it is forced into the ducts and cavities of the gland, which thereby become enlarged, the muscular coat of the bladder being also gradually thickened. In these circumstances, if prostatic calculi exist, they will readily increase, owing to the passage of urine over them, or the stagnation of it around them; but when the ducts and cavity become thus dilated, and admit the urine during efforts to expel it, the calculi may actually form in the prostate from the urine thus propelled into and accumulated in the cavities of the gland. I consider that calculi may form in the prostate, or be found either altogether or partly in it, as follows: 1st. They may form in the gland, or in its ducts, independently of any access of the urine, or deposit from this excretion; and in this case they are small and numerous, consisting chiefly of the

carbonate or the phosphate of lime, with a large proportion of animal matter. 2d. Calculi may form in the ducts and cavities of the gland consecutively of stricture of the urethra, owing to the passage into and stagnation of urine within these parts, as shown above; and may afterward increase so as to be partially external to the gland; in this case they may be similar, in chemical constitution, to other urinary calculi, according to the existing calculous diathesis, and may reach a large size. 3d. They may originate in the first of these modes, and subsequently increase greatly in size, owing to urinary deposit, as in the second mode. 4th. Fragments of calculi may escape into dilated prostatic ducts or cavities after lithotomy, or small gravelly calculi may pass into the ducts independently of this operation, where they may increase, as in the second mode of formation.

34. The first or true prostatic calculi vary in size from that of a pin's head to that of a pea, and in number from eight, ten, or twelve to forty or fifty. They are often attended by little inconvenience until they obstruct the excretion of urine; but, in rare instances, they occasion distressing irritation and excitement. Two remarkable cases of prostatic calculi are reported by Dr. HERBERT BARKER (*Trans. of Provin. Med. and Surg. Assoc., N. S.*, vol. ii.), and by Professor FERGUSSON (*Lond. Med. Gaz.*, Jan. 7, 1848). The calculous deposit was most probably formed, in these cases, in the second of the modes now pointed out. Indeed, Professor FERGUSSON mentioned to me, that this was the probable mode of their formation in the case operated upon by him, as they were preceded by stricture of the urethra. Dr. PROUT believes that the larger calculi, which are smooth and polished, and have a porcelain-like appearance, always originate in abscess of the prostate, but it will be found that they are formed in the cavities of the prostate consecutively of stricture of the urethra, as shown above.

35. Dr. CROSSE, of Norwich, remarks, that "it is only when large or numerous in one large cyst, or projecting into the urethra, that prostatic concretions give rise to the symptoms of stone; frequent painful micturition, and discharge of mucus from inflammation of the urethra and neck of the bladder. They seem to be sufficiently often combined with stone in the bladder to lead us to suspect that the one disease contributes to the production of the other; and, indeed, I consider that urinary calculi, stricture of the urethra, or whatever other diseases here situated, causing inflammation of the prostatic part of the urethra, and interrupting the free exit of the excretion of the prostatic ducts, dispose to the formation of calculi of this description." These observations, by so learned and experienced a surgeon, show the connexion I have contended for; while his subsequent remarks indicate that the third mode in which I have viewed the formation of those calculi (§ 33) is one to which he most justly attaches great importance, although he generalizes more in respect of them than agrees with my views. "A distinction to be kept in mind in respect of prostatic calculi is," Dr. CROSSE observes, "that they are not urinary concretions, but are formed and may increase without the urine having access to them; they may,

notwithstanding, rise to the orifice of the prostatic ducts, or get into, or be detained in the urethra, or pass retrograde into the bladder, becoming the nuclei around which deposits from the urine take place." This is one of the modes of formation which I have enumerated, and I could not have an abler authority upon which I might found my views.

36. *B. The Diagnosis of prostatic calculi* is seldom very clear, unless the calculi are large or numerous, or project into the urethra or bladder. Mr. COULSON justly observes, that "a retention of urine or pain about the neck of the bladder, and frequent desire to make water, are sometimes the only symptoms; and these are common to several other affections of the prostatic gland urethra." *Per anum* the gland may be felt to be enlarged; and, in some instances, the calculi may, by their number, form, or size, furnish sufficient evidence of their presence, as in a case mentioned by Dr. MARCET, where they could be plainly felt through the coats of the rectum. When the calculi project from the gland into the urethra, the sound will strike against it; but it will still be a question whether or no the calculus be one which has passed out of the bladder into the urethra. The history of the case, and the existence previously and at the time of symptoms referable to the prostate, will be the chief guides to a diagnosis.

When they strike or grate against an instrument, they will occasion sensations in both the prostate and perinæum, and in the *glans penis*, which will indicate their nature. When very large or numerous, they may be felt, as if in a cyst, *per anum*, or they may protrude so as to be felt in the perinæum.

37. *C. Treatment.*—When severe symptoms are produced by prostatic calculi, then dysuria, stricture, sacculi, inflammation, and thickening of the coats of the bladder all ensue; and in extreme cases, and when it is fully ascertained, upon the requisite examinations, that large or numerous prostatic calculi are present, it will be right, as advised by Dr. CROSSE, to cut down to the prostatic gland from the perinæum, as in the lateral method of litho-cystotomy, and to remove the concretions. An interesting case, recorded by Mr. COULSON (*Op. cit.*, p. 273), will farther illustrate the treatment, which is entirely surgical; and to this, as well as to the remarks of other eminent writers noticed in the *Bibliography*, I must refer the reader.

38. vii. CONCRETIONS FORMED IN THE VEINS, about the prostate gland and neck of the bladder, have been noticed by MECKEL, TIEDEMANN, OTTO, LEBSTEIN, and CROSSE. The last-named author states, that "in aged persons, particularly with hypertrophy of the prostate, a bladder diseased, and the veins about it and the rectum varicose, concretions of phosphate of lime or carbonate of lime, varying in size from a pin's-head to a kidney-bean, are often found in the veins." Sometimes they present the appearance of a white pea, and an inequality or projection answering to the part by which they adhered to the vessel. These concretions have no connection with urinary or other excretions, and are merely growths or concretions which had been adherent to the coats of the vein. They approach nearer to ossific than to calculous concretions. (CROSSE, *Op. cit.*, *passim*.)

39. viii. THE COMPLICATIONS of organic le-

sions of the prostatic gland are those already noticed (§ 16), especially inflammation and thickening of the coats of the bladder; structural lesions of the kidneys, strictures of the urethra, gleet, and gonorrhœa; involuntary pollutions; the several diseases of the rectum, particularly hemorrhoids, prolapsus ani, stricture, or scirrhus; constipation and various affections of the colon, hemorrhage from the urinary bladder, or from the urethra, or from the rectum, and intestinal worms.

CLASSIF.—6th Class, 3d Order (Good). 1st Order, 3d Genus (Willan). III. CLASS, I. ORDER (Author in Preface).

1. DEFIN.—An eruption of papulæ, larger than those of lichen, not materially differing from the colour of the skin; attended by excessive heat and pungent itching; becoming covered with small black scabs when scratched or abraded; leaving behind them yellowish stains; very chronic in duration, but not contagious, and generally unattended by fever.

2. This eruption generally appears about the neck and shoulders, and sometimes extends to the face, trunk, and limbs, more especially to the back; and to the outer sides of the arms and thighs, in the line of extension, and assumes a severe character. It is occasionally confined to a single spot. Its mildest forms may decline in the course of three or four weeks; but much more frequently it continues several months, or even years, and is attended by a burning and intolerable itching. WILLAN has distinguished three varieties, which may be modified in certain localities, or be limited to these localities, thus assuming three local forms. The varieties, according to WILLAN and other writers, are *Prurigo mitis*, *P. formicans*, and *P. senilis*. The first and second differ from each other merely in degree, there being no fundamental distinction between them. The third variety has some peculiar characters.

3. I. DESCRIPTION.—i. *Prurigo mitis* appears in the form of small and slightly prominent papulæ, broader than those of lichen, soft and

smooth to the touch, and of the same colour as the skin. They are attended by incessant itching, which is greatly increased upon the removal of the clothes, by changes of temperature, by the warmth of bed, and by exercise. When left to themselves, or not aggravated by scratching, or by a heating regimen, they subside, with a slight exfoliation of the epidermis; but more commonly the relief of the pruritus attempted by scratching causes the removal of the tops of the papulæ, which then become covered by a small characteristic black scab, formed by the drying of a minute exudation of blood on the abraded spot. If the papulæ be much irritated, oethymatous pustules are sometimes developed. This form of the eruption is most frequent in the spring and summer months in the situations above mentioned (§ 2). It is often preceded by slight disorder of the digestive and excreting functions, especially of the latter, and occasionally by slight acceleration of pulse; but these are usually overlooked. The mildest cases may terminate in about three weeks; but more frequently fresh papulæ appear as the preceding vanish, and the eruption may thus be prolonged for several months.

4. ii. *Prurigo formicans* is merely a severer form of the preceding. The papulæ are, however, generally larger—broader and more prominent, yet flat. They are distinct, nearly of the colour of the skin, if not torn by the nails, and commonly seated on the neck, back, loins, and external aspect of the limbs, although they may appear also on other parts. They are sometimes very numerous in young subjects. The itching is more severe and pungent than in the first variety, resembles the gnawing of innumerable ants or the pricking of hot needles, and is increased towards evening by the heat of bed, and by the circumstances already noticed. RAYER remarks, that patients describing their feelings liken them to burning fires and maddening itchings. ALIBERT says that PLATO, CHARLES V., CHARLES IX., and other great men, were afflicted with this eruption; and that the Abbé MORELLET, at the age of eighty, expressed himself as writhing on "St. LAWRENCE's gridiron" when suffering from it. The warmth of bed sometimes increases the itching to such a pitch as to cause the patients to scratch themselves until they bleed, and as to prevent sleep until morning, or until exhaustion sinks them into it; when they often soon awake to be similarly tormented. The black scabs following the scratching are frequently the chief appearance of eruption, although redness of the skin is often produced for a short time by the scratching. The affection continues for months, and, with varying remissions or intermissions, often for years, especially in weak children and adults, and in old persons. After the subsidence of the eruption the skin remains dry and thickened, and the epidermis exfoliates. This form of the complaint is generally preceded by disorder of the abdominal organs, and by slight fever, which tend to complicate and perpetuate it. Like numerous other cutaneous affections, it should be viewed as a local manifestation of disorder implicating the excreting functions and the state of the circulating fluids, and requiring a treatment directed accordingly. It may occur in both children and adults at any period of the year.

5. iii. *Prurigo senilis*, or *Senile prurigo*, closely resemble prurigo formicans; but the papulæ are harder, larger, and more confluent. It is attended by incessant and insupportable itching, and may endure for years, with varying severity. The papulæ are intermingled with small black scabs and numerous scratches, caused by attempts to relieve the pruritus. In more prolonged cases the skin becomes swollen, inflamed, and as if thickened; and the affection is sometimes complicated with eruptions of vesicles, pustules, or boils, according to the constitution and regimen of the patient. Abscesses are even occasionally formed. But these external associations generally proceed from more or less marked disorder of the assimilating and excreting functions, more especially of the liver, bowels, and kidneys, with or without gastro-intestinal irritation or febrile excitement.

6. In a severe case of senile prurigo, WILLAN found a number of minute *pulices* upon the skin, and he remarked the frequent association of the *pediculus vestimentorum* with this eruption. In very old persons, or in the debilitated, when the eruption follows febrile diseases, and in those who live on poor, unwholesome food, but especially in debilitated persons in the decline of life, swarms of *pediculi* not infrequently complicate this affection. There is, however, also more or less disorder of the abdominal functions, with either a poor or impure state of the circulating fluids.

7. iv. *Local Forms*.—These are merely the occurrence or limitation of prurigo—of its characteristic eruption, to certain localities, where it usually becomes severe and prolonged, and occasionally produces additional annoyance or distress. In the several localities constituting these forms, the eruption is similar to some one of the varieties already described; the locality favouring no one variety more than another.—*A. Prurigo podicis* is generally an eruption of papulæ similar to those of *P. mitis*, but more frequently to those of *P. formicans* around the anus, sometimes extending to the perinæum, between the nates and thighs. The symptoms and duration of the eruption are the same as stated above. After its long continuance the skin around the anus becomes rough, thickened, and otherwise altered.—*B. Prurigo scroti* is merely the extension of the eruption to the scrotum, and is not farther peculiar in any respect, the symptoms and sufferings being the same as in the several varieties.—*C. Prurigo pudendalis* is seated chiefly in the *labia majora* and mucous surface of the *vulva*. It is attended by constant but varying pruritus, occasioning swelling or inflammation of the parts, sometimes with a serous exudation; and it induces sexual excitement and self-pollution, amounting in some instances to nymphomania. This form sometimes occurs during pregnancy, and occasions much misery.

8. II. *DIAGNOSIS*.—Prurigo is distinguished by the absence of colour from the papulæ, and by the stinging or burning pruritus. It may, however, be confounded with *lichen* and some of the *vesicular eruptions*.—(a) It is distinguished from *lichen* by the larger size of the papulæ, by the small black scabs, and by the intense burning itching.—(b) Prurigo is most likely to be confounded with *scabies*, but the papulæ of

prurigo are flattish and of the same colour as the skin, while the vesicles are acuminated and rose-coloured. The vesicles of the latter terminate in yellow scabs, and occur in exactly opposite situations to those in which prurigo appears, namely, in the internal surfaces of the limbs and in the line of flexion. The pruritus of scabies is also much more supportable than that of prurigo.—(c) Prurigo may co-exist with lichen, scabies, and eczema, and with the pustules of impetigo and ecthyma. It terminates by resolution or by furfuraceous desquamation.

9. III. PROGNOSIS.—Prurigo is not attended by danger in the young, robust, or otherwise healthy, although it may prove very obstinate and harassing to the patient. In debilitated, cachectic constitutions; in old and ill-fed persons; and where cleanly habits are not duly observed, it is often incurable; and if it be associated in these with visceral disease, it may tend to shorten life. In the complications especially, and particularly in those with disorder of the abdominal organs, either the suppression of the external eruption, or the development of acute disease of these organs, may be attended by severe or dangerous symptoms, especially if the eruption disappear rapidly.

10. IV. CAUSES.—The first and second varieties of prurigo occur chiefly in children and adults, and at all seasons, but more frequently in spring and summer. Senile prurigo is most common in the old, ill-fed, and in connexion with an impoverished or impure state of the blood. Low and damp situations; poverty, and the want of cleanliness; unwholesome, deficient, or poor diet; the use of salt, stale, or dried, or otherwise preserved fish, or of shell-fish; heating and stimulating liquors and condiments; impaired excreting functions, especially by the liver, bowels, kidneys, and skin; the neglect of aperient or chologogue medicines, and of due evacuations; visceral disorders occasioning, or even consequent upon, the accumulation of effete materials in the circulation; the suppression or interruption of various depurative functions, as amenorrhœa, &c.; the use of dirty clothes, or of foul woollen bed-clothes, and of foul or impure beds, stuffed with animal productions, as wool or feathers which have become contaminated by the perspiration of many years of occupation; the influence of mental emotions, and interruptions of the excreting functions, severally and in various states and forms of association and succession, occasion this and various other chronic eruptions.

11. V. TREATMENT.—In all cases, especially the more protracted, of this complaint, the state of the abdominal viscera, and of the several excretions should be closely examined, and existing disorder of these corrected or removed.

—A. If abdominal plethora or congestion of any of the abdominal viscera be present, a moderate vascular depletion may be prescribed; and PLUMMER'S pill with soap be given at bedtime, and an aperient in the morning, consisting of the electuary of senna with magnesia and milk of sulphur. A dose of a bitter infusion, as calumba or chereita, may be taken once or twice daily, with the sesquicarbonates of potash and ammonia. Having removed accumulated or morbid excretions, and promoted the discharge of effete materials from the blood, the healthy

functions of the skin should be restored by a frequent use of warm alkaline, or of soap, or of sulphur baths; and by the internal administration of sulphur with magnesia, or with an alkaline carbonate, every night, or both night and morning. When the skin is dry and rough, these baths may be alternated with vapour baths, or with baths containing the bi-borate of soda, and followed by warm baths with gelatin or mucilaginous substances, as tragacanth, two or three days being allowed to elapse after the mucilaginous baths in order to observe their effects. These last baths may likewise contain either of the alkaline sub-carbonates, from one to four ounces to each bath, according to the size and age of the patient. Where the skin is delicate and irritable, then irritating baths and applications ought to be avoided; simple warm or soap baths, or gelatinous, emollient, or mucilaginous baths being most serviceable. If these fail, the state of the assimilative and excreting viscera should be strictly examined, in order to detect lurking disorder; for generally to this cause is the obstinacy of the complaint owing, and to it, also, are to be imputed the injurious and often dangerous consequences of suppressing the eruption before, or without, attending sufficiently to the states of the abdominal functions and organs.

12. Various ointments and greasy or oily applications have been recommended for this eruption, especially those containing sulphur, the iodide of potassium, and muriate of ammonia; but independently of the unpleasantness of such applications to an extensive surface, they soon become, owing to the action of the air upon them, more or less irritating, although they may at first have afforded a little ease. If they be at all prescribed, they ought to be followed, in eight or ten hours, by a warm saponaceous or emollient bath. Instead of these I have generally employed a lotion with the hydrochlorate of ammonia; or a very weak solution of the bi-chloride of mercury, with or without the vinum opii, or watery extract of opium; or a solution of the sulphuret of potash; or a solution of the bi-borate of soda, or chlorate of soda or potash, or of the alkaline sub-carbonates, or diluted pyroligneous acetic acid, with the addition of creasote. These are severally beneficial; and while camphor-water, rose-water, or elder-flower water may be used as the vehicles of the active agents, opium, or hydrocyanic acid may be added, according to the circumstances of the case. In the more obstinate cases, I have prescribed, after due attention to the abdominal functions and organs, a weak solution of the iodide of potassium, with a watery solution of opium, as a lotion, and sometimes also this iodide or the iodide of iron internally, with sarsaparilla or with taraxacum, and have observed much benefit accrue from the treatment.

13. B. The senile variety of prurigo will generally be removed, if it be capable of removal, by the means above recommended, especially if due attention be paid to the states of the several excreting viscera, and to diet and regimen. The utmost cleanliness should be observed, and as there is often not only debility, but also anæmia, or an impoverished state of the blood, in these cases, tonics and chalybeates should be associated with carbonate of ammonia, or

with either of the other alkaline carbonates in the treatment. The patient should sleep on a hair mattress; and the bowels ought to be duly regulated by means of sulphur with magnesia, or of any stomachic aperient which may be found to agree the best, as the infusions of gentian and senna with the sesquicarbonates of ammonia and of soda.

14. When the eruption is associated with the production of *pediculi*, a tonic treatment is more especially required, aided by cinnabar fumigations, or by frequent sulphur baths, or by lotions with the bi-chloride of mercury. A trial, in the most obstinate cases, may be given to mineral waters, especially when the excreting organs are torpid. The waters of *Cauterets*, or of *Bonnes*, or of *Bareges*, or of *Carlsbad* may be taken. Of these the *Bareges* water may be preferred; but I believe the sulphureous waters of *Harrogate*, or of *Gilsland Spa*, or of *Moffat* to be equally, if not more beneficial in this complaint, aided by warm bathing, due exercise, and appropriate diet. While the diet is sufficiently nutritious, it ought to be digestible; and fish, shell-fish; pork, veal, ham, bacon; heating condiments and rich sauces, coffee, and stimulating beverages should be avoided.

15. *C. The local varieties* require chiefly the means already noticed.—(a) *Prurigo podicis* and *P. scroti* are often connected with chronic irritation of the rectum and of its mucous follicles, owing either to the presence of *ascarides* or to *hemorrhoidal affection*. In these cases, small injections of some of the lotions above mentioned into the rectum; great attention to cleanliness; the treatment, local and general, advised for these diseases; the application, by means of a sponge, of the lotions already enumerated (§ 12), or of a weak solution of the acetate of lead with vinum opii, especially immediately after each stool; local fumigations with sulphur or cinnabar, and an occasional application of leeches in plethoric persons, will seldom fail to remove the complaint, which, however, is very prone to recur, after neglect or errors of diet and regimen.

16. (b) *Prurigo pudendalis* being sometimes occasioned by disordered catamenial functions, or by leucorrhœa, or by pregnancy, and complicated with either of these, requires an especial reference to the existence or non-existence of either. In these cases, the internal, external, and dietetic means already specified are of more or less service; but in these complications they may all fail, and the patient be reduced to a state of great misery. Treatment often fails during pregnancy, although the complaint will generally disappear after delivery. In some cases it has recurred in each pregnancy, and has even reappeared after the change of life. The application of leeches to the vulva; cooling aperients and enemata, and cooling and detergent injections *per vaginam*, or similar lotions to the *vulva*, are commonly of use. It is not rare to find this variety associated with one or more small boils of the labia majora, and in these cases the lead lotion with vinum opii will remove the affection at any early stage, and poultices or warm fomentations afford relief at a more advanced state. *Prurigo vulvæ* has generally disappeared, after the use of a lotion consisting of a saturated solution of the bi-borate of soda in rose or elder-

flower water, either with or without the addition of the vinum opii, or of the pure acetic acid, or of both.

PRURITUS.—SYNON. *Hyperæsthesia cutis*—*Itching*, morbid sensibility of the skin—*Prurit*, *Démangeaison*, Fr. *Das Jucken*, die *Reitzbarkheit*, Germ.

CLASSIF.—III. CLASS, I. ORDER. (Author in Preface.)

1. DEFIN.—*Itching over a greater or less extent of the cutaneous surface, or limited to a particular part without any perceptible eruption, and generally symptomatic of some internal disorder.*

2. Pruritus, more or less general, is usually symptomatic of disorders of the digestive organs, or of some irritation of the digestive canal, especially intestinal worms. In these cases, the irritation of the mucous surface is propagated to, or reflected upon, the extremities of the nerves supplying the skin. The itching is often annoying, and is generally remittent; but it often continues in this form for many months. It is exacerbated by the same causes as those which increase prurigo, especially by changes of temperature, by stimulants and heating condiments, by hot spices, by opium, and by directing the attention to it. In some idiosyncrasies, various articles of diet or of medicine occasion it; and then it usually continues only for a short time. Shell-fish, or fish of any kind; smoked, dried, or preserved meats, &c., sometimes cause it. It is not infrequently a symptom of disorder of the uterine discharge of hysteria; of the slighter states of irritation of the spinal chord or membranes, and of several eruptions.

3. i. *The local or limited states* of pruritus or itching may arise from the same causes as those now mentioned, but they much more frequently proceed from others more immediately connected with the seat of itching. In most instances, however, of local pruritus there is more or less functional disorder of the digestive organs, or accumulation of fecal or excrementitious matters.—(a) *Pruritus nasi* is often sympathetic of intestinal worms, and even of ascarides in the rectum, or of fecal collections in the large bowels, or of dyspeptic disorders.—(b) *Pruritus urethræ* is often a very troublesome affection. Itching of the extremity or course of the male urethra is most frequently caused by calculus or gravel in the bladder, or by irritation of the prostate gland or stricture of the urethra. In females it is connected either with calculus in the bladder, or with leucorrhœa or uterine disorder.—(c) *Pru-*

*ritus vulvæ* is often a most distressing affection. It is seated chiefly in the labia majora, but it frequently implicates the clitoris and nymphae, or even extends up the vagina. It is usually caused by ascarides in the rectum, by disorder of the catamenia, by leucorrhœa, by self-pollution, and by hemorrhoids. It is not uncommon during the periods of puberty and the cessation of the menses, and especially during pregnancy.—(d) *Pruritus ani* is often a very troublesome and obstinate complaint, and is most annoying soon after retiring to rest. It is usually caused by ascarides in the rectum, by hemorrhoids, by fistula ani, by neglect of cleanly habits, by morbid states of the intestinal secretions, especially of the mucous follicles of the rectum, and by irritation or congestions of the prostate gland and vesiculæ seminales. It is often complained of by persons of sedentary occupations and habits, and by those who sit on soft and warm cushions. The itching, although occurring independently of any visible eruption, when repeated or protracted, often occasions slight excoriations and thickening around the margin of the anus.

4. ii. *Diagnosis*.—*Pruritus* can be confounded only with *prurigo*, from which it is distinguished by the absence of any visible eruption, unless such redness, or excoriation as may result from scratching, and the mechanical irritation employed to remove or relieve this annoying sensation.

5. iii. *Treatment*.—This should be directed to the removal of the morbid condition of the viscera, upon which the pruritus depends. This is most effectually accomplished by occasional doses of spirits of turpentine and castor oil, and by enemata of the same, so as fully to evacuate all accumulated or morbid matters from the bowels. Afterward the lotions I have prescribed for *PRURIGO* (§ 12), especially the lead lotion with opium; diluted vinegar or lemon-juice with creasote; a weak solution of bichloride of mercury with some hydro-chlorate of ammonia; or the solution of the biborate of soda. Attention should be directed, in the treatment of the pruritus of females, to the state of the uterine functions, which ought to be duly promoted; and when congestion of the uterine organs, or of any of the abdominal viscera, is present, especially if the patient be young and plethoric, or if the parts become hot or excoriated, then local depletions, followed by hot fomentations, are required. The diet, regimen, and treatment are in most respects the same as advised for *PRURIGO*.

PSOÆ MUSCLES—INFLAMMATION AND SUPPURATION OF.—SYNON. *Psoitis*, Auct. Lat. *Psoite*, *Inflammation des Museles lombaires*, Fr. *Entzündung der Lendenmuskeln*, Germ. *Psoas abscess*; *Lumbar abscess*.

CLASSIF.—III. CLASS, I. ORDER. (See Pref. acc.)

1. DEFIN.—i. NOSOLOG.—*Pain in the loins, generally on one side, commencing and existing insidi-*

*ously, but often becoming severe, and extending to the hip, thigh, and knee-joint, caused by inflammation and suppuration, the pus collecting around the muscles, and descending with more or less tumour, either under POUPART'S ligament or in some other direction.*

2. ii. PATHOLOG.—*Inflammation of the cellular tissues surrounding the psoæ lumbar and adjoining muscles, generally originating in caries of the bodies of the vertebræ, or in inflammation of the intervertebral substance, the muscles themselves ultimately becoming disorganized, and the purulent collection gravitating in the course of the cellular tissue, and opening or forming a tumour as above and as hereafter stated.*

3. I. THE CAUSES OF *Psoas* or *lumbar abscess* are, the scrofulous, the rheumatic, and the gouty diathesis; a cachectic habit of body, tubercular changes or deposits in the bodies of the vertebræ; caries of the vertebræ, especially the lumbar; inflammation of the intervertebral substance; violent exertion of the lumbar muscles, external violence, severe strains, or sudden jerks or twists of the loins; currents of cold air on the back or loins; and ulcerations of the cæcum extending to the peri-cæcal cellular tissue. Caries of the dorsal or lumbar vertebræ, or inflammation of the intervertebral spaces are the most common causes of psoitis and lumbar abscess. Of nineteen cases detailed by ABERNETHY, only two were independent of disease of the spine. He observes, that the general opinion of surgeons, in which he entirely concurs, is, that lumbar abscesses most frequently arise from diseases of the vertebræ; and they should certainly all be treated as if such were their origin.

4. II. SYMPTOMS.—*Psoitis* sometimes occurs suddenly, and the patient complains of pain in the loins, especially on one side. Walking becomes troublesome; the thighs can be neither raised nor extended without pain. The disease sometimes commences gradually, with pricking pains, which, becoming more severe, extend to the hip, and to the thigh, and even to the knee-joint. Sometimes the progress of inflammation is so insidious as hardly to be noticed, until the mischief appears in the form of a purulent collection. According to the extent of vertebral disease and the degree of inflammation does suppuration appear early or late; but the abscess which is formed generally assumes a chronic state, and is of a symptomatic character, as it is consecutive of inflammation and caries of the vertebræ. The chronic abscess, termed *psoas* or *lumbar abscess*, commonly forms in consequence of disease of the vertebræ of the back or loins. Matter is secreted around the diseased vertebræ, and then descends through the loose cellular tissue covering the muscles along the side of the pelvis into the thigh. It may take a course towards the back, or may go in various directions either within or without the pelvis. The pus formed about the seat of caries remains there for a longer or shorter time, especially in the cellular tissue. As the pus collects and increases it forms a cyst, which descends, and lengthens as it inclines to either or to both sides of the vertebral column. As the pus accumulates it pushes onward the lower end of the cyst, which, if it meet with any obstacle, spreads out, but contracts when pressed on by the adjoining parts, and dilates again

when relieved from pressure, until it at last arrives at the place, when it projects or breaks. In the route which the purulent matter thus takes, the psoæ and other lumbar muscles are inflamed, pressed upon, partially absorbed and disorganized, owing to the extension of the inflammation and purulent infiltrations to them and their connecting cellular tissue.

5. The abscess most frequently protrudes below POUPART'S ligament, and it generally extends or opens at a greater or less distance from the original seat of disease. It may, however, point or open into the cæcum, into the colon, or the rectum, or in some part of the back, or in the loins just above the sacrum; or it may make its way to the hip, or the groin, and proceed even down the thigh in the direction of the large vessels. As the matter is seated behind the peritonæum, and as it generally gravitates according to the position of the body, it very rarely perforates this membrane and becomes effused into the abdominal cavity. As the purulent matter increases and presses upon, or otherwise implicates, or even inflames the larger veins, nerves, or arteries, so are the symptoms either of phlebitis, or of neuritis, or of arteritis, according to the situation and extent of the abscess, not infrequently superinduced, and complicated with the advanced progress of the disease, in addition to the primary lesion of the spine. I have repeatedly met with these complications, which have greatly aggravated the sufferings of the patient. If, during its increase, the abscess breaks externally, or is opened so as to admit the air, pus is discharged, at first without smell; but it subsequently becomes offensive, and the hectic symptoms more marked. The powers of the patient sink, and the stomach becomes irritable. In some cases the aperture either closes, and matter again collects, or it contracts, and remains fistulous for a considerable time.

6. III. DIAGNOSIS.—(a) During the formation of matter the patient suffers pain in the loins, and walking is painful. When the abscess is not large, the usual symptoms of suppuration may be absent, or so slight as to escape observation. Night or morning sweats, emaciation, and other hectic symptoms, however, generally appear or increase with the progress of the complaint. When the purulent collection has increased so as to form an external tumour either in the groin or in the loins, or near the anus, a movement may be perceived in it upon coughing. When the matter has gravitated towards the thigh or anus, the tumour is lessened by the recumbent posture. If the patient has suffered continued pain in the loins for four, five, or six months; if he has difficulty in extending the thigh, especially when putting his legs together; if he feels pain and tightness in the groin, and increase of pain on attempting to exert the limb, or when the psoas muscle is either put on the stretch or exerted, then this disease should be suspected, even although no external tumour has yet appeared; but if such tumour is present, there can be little doubt of its nature.

7. (b) Psoas abscess, when protruding under POUPART'S ligament, may, as Mr. SOUTH observes, be mistaken for femoral hernia, especially as it dilates on coughing, and partly subsides when the patient lies down. But it is generally

of larger size than femoral rupture, and the fingers cannot be at all thrust around it, as they partially may behind the hernial sac. The chief distinctions, however, are the long continuance of pain in the loins previously to its appearance, the persistence of that pain, and the remarkable increase of pain produced by attempting to extend the thigh, especially backward, or the entire inability to do so. "When the abscess appears in the loins, there is no difficulty in determining its character by its history, and by its dilatation on coughing. Pulsation may sometimes be communicated to it from the adjoining large vessels;" and thus it may be mistaken for aneurism, if the history of the case and the existing symptoms be not attentively investigated.

8. (c) The diagnosis between psoas abscess and disease of the hip-joint is not always, although it is frequently, easy. It has been well pointed out by Mr. COULSON (*On Disease of the Hip-joint*, 4to, Lond., 1837, p. 72), and nearly as follows: 1st. In psoas disease, the patient generally complains of dull or of severe pain in the loins, which is increased by the upright posture, and by every motion of the limb, particularly on extending it: in diseased hip there is no fixed pain in the loins; it is felt more in the vicinity of the hip, and especially in the knee. 2d. In the whole course of psoas disease there is no deviation in the natural situation of the trochanter, and no difference in the length of both limbs; in diseased hip, on the contrary, this is always the case. 3d. In psoitis and lumbar abscess the patient cannot turn the foot of the affected side outward without increasing the pain; in diseased hip the foot is generally turned outward. 4th. On taking a deep inspiration, on coughing, crying, and in the erect posture, the fluctuating swelling either in front of the thigh or on the nates increases, and exit of matter, if the abscess be open, is facilitated; but in abscess of the hip-joint neither phenomenon is observed.

9. IV. PROGNOSIS.—The prognosis of psoitis, especially when the inflammation has gone on to abscess, is extremely unfavourable. Professor COLLES states, that not one patient out of fifty recovers from it; and that, in the course of his practice, he has not known five cases in all recover. He never knew a case get well where a surgeon interfered at all with it. In my own practice, I know only of two recoveries. For these no surgical aid was required beyond the formation of an issue in the back or loins. When psoas abscess is complicated with tubercles in the lungs, or with paraplegia, or with phlebitis or neuritis, instances of such complications having occurred in my practice, the case is then hopeless. I may, however, add, that psoas abscess may become complicated with hip-disease, a case of this association—the latter supervening on the former—having been under my care; or hip-disease may give rise to psoas abscess, as shown by Dr M'DOWELL.

10. V. TREATMENT.—This disease usually appears so insidiously, and advances so slowly, that it has proceeded in most cases beyond the influence of treatment before medical aid is required. When it is recognised at an early stage, and especially when the lesions of the vertebræ are not far advanced, or the inflamma-

tion consequent upon them has not given rise to much suppuration, then reasonable hopes may be entertained from the use of appropriate means. If the powers of the patient be not reduced, if there be no sign of anæmia, or of impaired vascular action and tone, the application of leeches, or cupping in the vicinity of the vertebral lesion, according to the state of the case, should be prescribed, and aided by stomachic aperients and cooling diaphoretics, with suitable attention to diet and perfect quietude. After sufficient local depletion, I have generally directed either of the following embrocations to be applied to the back or loins by means of flannel, and renewed once in the twenty-four hours if it be found to agree; the sensations of the patient, the state of the pulse, and a careful observation of all the symptoms guiding the physician:

No. 325. R. Linimenti camphoræ comp.; Linimenti terebinthinæ; Linim. saponis cum opio, ʒā, ʒj.; Olei cajuputi, ʒj. M. Fiat embrocatio.

No. 326. R. Linimenti terebinthinæ; Linimenti camphoræ comp., ʒā, ʒjss.; Olei olivæ, ʒiij.; Olei cajuputi, ʒj. M. Fiat embrocatio.

11. If these embrocations fail, after local depletions and other constitutional or suitable means, to arrest the progress of the disease, open blisters in the vicinity of the part or issues ought to be ordered, and kept freely discharging; while an alterative and restorative influence should be exerted on the constitution by a course either of the iodide of iron with sarsaparilla, or of the iodide of potassium and liquor potassæ, with compound tincture of bark and fluid extract of sarsa; or of the bichloride of mercury, in either the compound tincture or decoction of cinchona. I have alternated short courses of these, varying them according to circumstances, during the operation of the applications, issues, &c., advised to be applied near the diseased vertebræ, and often with marked benefit. I have prescribed iodine for this disease since 1822.

12. Several surgical writers, even ABERNETHY, COOPER, DUPUYTREN, LAWRENCE, PEARSON, CHELIUS, SOUTH, and others, have directed their attention and their treatment chiefly to the consecutive abscess. But if the abscess be not large, if it be not complicated with paraplegia, or if it occasion no distressing symptoms, as it sometimes does, by its pressure on nervous, venous, or arterial trunks, or large branches, it should not be officiously interfered with; the external drains, &c., placed near the diseased vertebræ, the constitutional means prescribed above (§ 11), and such other aids as stomachic aperients, &c., as the peculiarities of the case may require, being the remedies most deserving of confidence. If these means succeed in even partially removing the spinal disease, the consecutive abscess, if not large, will either diminish or become absorbed, at least in some instances, as in two of those which have come under my care, and for which the above treatment, without opening the abscess, was pursued. In one of these cases the treatment sometimes consisted, during the intervals between courses of the above medicines (§ 11), chiefly of full and regular doses of either morphia or opium, which also were occasionally given with these medicines.

13. When the inflammation terminates in suppuration, and an abscess is formed, CHE-

LIUS remarks, that the absorption of the matter may be procured in some cases, although rarely, by issues or perpetual blisters in the loins, and by general treatment, which promotes the abdominal functions and the patient's strength. DUPUYTREN observes, that these abscesses may remain for years, and the pus either be absorbed, no trace of them remaining, or, after a time, they may increase, the skin covering them becoming inflamed and giving way. In rare instances, the pus may drain away and not be reproduced, or, after a longer or shorter time, it may be converted into adipocercous matter. These, however, are favourable terminations of rare occurrence. Much more frequently the abscess goes on increasing, either until it inflames and bursts the skin at the most prominent point, or until it opens into one of the hollow viscera, or until the distressing effects produced by it, as already adverted to, create a necessity for opening it.

14. Mr. SOUTH observes, that issues are most important aids in the treatment of psoas abscess, either before or after it has opened of itself or been punctured, and that no circumstance should prevent a recourse to them. He advises the issue to be made on the side of the spine opposite to that where the abscess is seated. If presenting in one of the lumbar regions, the issue should be made at the outer margin of the quadratus lumborum of the opposite side; but if there be abscess in both lumbar regions, issues ought to be placed above and below them. If the swelling appear at the top of the thigh, an issue may be made on the same side, or in both sides of the spine, but never over the spine, nor over the abscess itself, for very obvious reasons. The issue should be made the size of a sixpence, with caustic potash, and it will generally enlarge to that of a shilling: one, or both, should be kept freely open and discharging, as just advised, while the constitutional and restorative powers ought to be promoted by the means recommended above.

15. Much difference of opinion exists as to the propriety of opening psoas or lumbar abscess, or of waiting for the self-evacuation of it. My own observation leads me to state, that there are cases for which surgical interference is either unnecessary or injurious; while there are others for which it may be most beneficially employed, if not for a cure, at least for the alleviation of the sufferings of the patient, and prolongation of life. When required, the opening should be made, as advised by Mr. ABERNETHY, so as entirely to prevent the entrance of air through the aperture, otherwise inflammation of the sac, increased hectic, offensive discharge, and sinking of the powers of life will ensue. An opening thus carefully made, and subsequently managed as carefully, will often prevent those painful complications observed in the advanced course of the malady, and to which surgeons have not sufficiently adverted. The occasional inflammation and erosion of vessels adjoining the purulent collection, and the distressing symptoms which result, as well as the not unusual implication of a nervous trunk, or of some other important part, may be prevented, or even alleviated after their appearance, by opening the abscess before it has become so greatly distended as to complicate the case and increase the sufferings

of the patient. Mr. South has given a good digest of surgical opinions on this topic, with his own advice, and to his translation of Celsus's system of surgery I refer the reader respecting it. I should, however, add that, whether the abscess be opened or not, the issues and constitutional treatment I have recommended, with opium and other aids, and alternated, modified, or changed, as circumstances may require, ought to be persisted in throughout the disease.

**CLASSIF.**—4. Class, 8. Order (Cullen).

6. Class, 3. Order (Good). ii. Order,

2. Genus (Willan and Bateman). III.

Class, I. Order (Author).

1. DEFIN.—A chronic inflammation of the skin, either limited to a particular region or extended more or less over the surface, appearing first with slight elevations, which change into scaly patches; the patches of psoriasis being of different sizes, not depressed in the centres, but with irregular and very slightly raised edges; those of Lepriasis being generally rounded, slightly depressed in the centres, and surrounded by slightly raised and reddish circles.

2. Both *Psoriasis* and *Lepriasis* or *Lepra* were considered as modifications of the same disease by most of the ancients, and they are treated of by PAULUS ÆGINETA by the terms "*Leprosy and Psora*." He states that "both these affections consist of an asperity of the skin, with pruritus or wasting of the body, having their origin from a melancholic humour. But leprosy spreads over the skin more deeply in a chronic form, throwing out scales which

resemble those of fishes; but psora is more superficial and variously figured, and throws out furfuraceous bodies." (Translated by ADAMS, vol. ii., p. 15.) Mr. ADAMS concludes his remarks respecting the views of the ancients as to these affections as follows: "It will be remarked that the Leuce of the Greeks, the leuce and fourth species of impetigo of CELSUS, and the albaras of most of the Arabians, are the same as the *lepra vulgaris* of Drs. WILLAN and BATEMAN; that the alphos of most of the Greek authorities and of CELSUS, and the morphia alba of most of the Arabians, correspond with the *lepra alphoides* of our English nosologists; that the melas, alphos niger, and common lepra of the Greeks, CELSUS's third species of impetigo and his melas, and the morphia nigra and impetigo of most of the Arabian translators, apply to the *lepra nigricans* of our modern arrangement; and that the psora of the Greeks, CELSUS's second species of impetigo, and the scabies of OCTAVIUS HORATIUS, and of most of the Arabian translators, comprehend both the *psoriasis* and *scabies* of WILLAN and BATEMAN. Since many of the ancient authorities speak of scabies as being infectious, they must have applied the term to the true itch, with which it is not likely, as RAYER maintains, that they were wholly unacquainted. The earlier modern writers, as those of the Schola Salernitana, PLATERIUS, GUY OF CAULIAC, and LANFRANCUS, jumble together the Latin and Arabian names, so as to produce no ordinary degree of confusion." (*Op. cit.*, vol. ii., p. 21.)

3. I. CAUSES.—The causes of the several varieties of both *Psoriasis* and *Lepriasis* are the same, or the same causes are common to both these species.—A. The predisposing causes are chiefly hereditary conformation, the melancholic temperament, and an habitual languor and weakness of the circulation in the integuments, with dryness of the skin. These affections occur at all ages and in both sexes, but somewhat more frequently in adults and in those advanced in life. The influence of sex is not great, some writers stating that they are more frequent in females, others in males. They are both constitutional maladies, and are often connected with disordered abdominal functions, both at their origin and in their course. They are sometimes connected with the gouty and rheumatic diathesis, and they may appear at any season, but more frequently in spring and autumn: lepriasis oftener in autumn. Prolonged or neglected dyspepsia; inattention to the states of the bowels and of the intestinal secretions and excretions; the habitual retention or accumulation of fecal matters, improper and insufficient food; mental anxieties, and sexual excesses also predispose to these eruptions.

4. B. The occasional exciting causes are the use of salted, dried, smoked, or otherwise preserved meats and fish; the frequent use of shell-fish; irregularities and improprieties of diet, the use of pork or the flesh of the wild boar, bacon, hams, &c.; drinking cold fluids when the body is perspiring; vicissitudes of temperature and weather; poor, innutritious, or unwholesome food; exposure to cold or moisture, and living in low, damp cellars or localities; prolonged anxiety of mind; the frequent use of heating and stimulating food, sau-

ces, spices, condiments, pickles, preserves, acids, or spirituous liquors; debaucheries or excesses of any kind; the want of sufficient personal cleanliness; and the irritation produced by various substances employed in several of the useful arts.

5. The *contagious or non-contagious nature* of these eruptions has long been a topic of dispute, especially as they appear in countries bordering upon the Mediterranean Sea. My friend and colleague, Mr. DENDY, has considered the subject very fully in his unpublished work on these maladies, which he kindly allowed me to peruse; and concludes that in this country they are not contagious. WILLAN has observed that *psoriasis guttata* and *annulata* affect several children about the same time in large families and schools, especially those who sleep together; and the same remark is made by Mr. E. WILSON and others. The simulation of contagion must, however, arise from the constitutional predisposition to these eruptions undoubtedly existing in some families, and from the simultaneous operation of the same exciting causes. The topic, however, deserves farther investigation.

6. I have observed these eruptions more frequently in unmarried than in married females. They are often dependent upon impaired digestion and assimilation, and upon equally impaired function of the skin, kidneys, and intestinal canal, the blood thereby abounding in imperfectly assimilated chyle and in effete materials. I have seldom observed them in females whose catamenial discharges were quite regular and sufficient, these discharges, when healthy, being manifestly depurative as respects the circulation, and no mean preventive of chronic cutaneous eruptions. Many modern pathologists have viewed both *psoriasis* and *lepriasis* as symptomatic of gastro-intestinal irritation. That there is more or less disorder of the digestive canal in most cases of both these eruptions must be admitted; but it does not strictly follow that this disorder consists of inflammatory irritation. It is generally functional merely—a defect of function as much as disorder of function, the digestive and assimilative derangement and the cutaneous affection proceeding from the same source, viz., impaired organic nervous power, the cutaneous disorder only being the last of the series of functional and morbid changes.

7. Every arrangement of the scaly eruptions must necessarily be, to a certain extent, conventional, and be based on the more prominent phenomena and differences which they present. The chief points of difference have thus become the most familiar, as being the most commonly noted and represented, while the gradations by which the one variety and species pass into the other are so far kept out of view as to be either overlooked or unacknowledged. That this is the case more especially with the three species of scaly eruptions to which the terms of *pitryiasis*, *psoriasis*, and *lepra* have been applied is not to be doubted by any one whose knowledge of them has been acquired from observation, and not from writers who have been more anxious to create distinctions than to trace resemblances. That these three species of eruption do not merely present points of resemblance in most cases, and even of identity

in others, but also originate in the same or similar causes, will be farther admitted. Nor are their causes only the same, their constitutional nature, their associations, and their tendencies are also the same or closely similar. Still, it becomes necessary to describe those differences which may be remarked in their external characters, and which enable us to recognise as well as to classify them. The intimate connexion subsisting between these eruptions is shown by the circumstance of their presenting, in some cases, the distinct features of *psoriasis* in one part, and in another part those of *lepriasis*; and it occasionally happens that *pitryiasis* of very long duration, or the acute or inflammatory form of that species, when it becomes very chronic, assumes the form either of *psoriasis* or of *lepra*, while *lepra* of long duration often passes into the form of *psoriasis inveterata*. The three species of eruption, moreover, require the same constitutional and local treatment. For these and other reasons mentioned when treating of *tubercular leprosy*, or the *leprosy* of the Arabians and Middle Ages (*see art. LEPROSY*), I have viewed *lepra* as merely a species belonging to the same genus as *psoriasis* and *pitryiasis*; and have treated of *psoriasis* and *lepra* in connexion, their causes, pathology, and treatment being the same.\*

\* My colleague, Mr. DENDY, whose experience in the treatment of these eruptions is very great, has endeavoured to clear up the confusion, existing even down to the present day, respecting squamous diseases. He has arranged *psoriasis*, *lepra*, and the inflammatory form of *pitryiasis* as species constituting one genus, "*Lepriasis*," and has assigned to each species what he considers its synonyme in ancient and modern authorities. His views, as well as his descriptions, are most deserving attention. I give his arrangement, but I take the liberty of placing his species, "*Lepriasis furfurans*," or acute *pitryiasis*, before the other more chronic and severe species, consisting of *psoriasis* and *lepra*.

## 8. II. DESCRIPTION.—i. PSORIASIS GUTTATA.

—SYNON. *Lepra alphoides*; *Lepriasis albida*, Good. *Psoriasis discreta*, Rayer. *Dartre squameuse orbiculaire*, Alibert. *Lepriasis guttata*, Dendy. *Guttated dry scall*.—Psoriasis, even in this the mildest of its forms, is often preceded or attended by symptoms of indigestion, lassitude, and inaptitude for physical or mental exertion; but these are often so slight as to be overlooked. In this variety numbers of small, distinct elevations or papulæ occur, sometimes appearing at first of the size of a pin's head, their summits soon becoming covered with a minute scale of a dull white colour. These elevations are generally, at first, from two to three or four lines in diameter, irregularly circumscribed, and generally rounded. They increase somewhat in size, but always remain distinct, with the skin sound between them. When freed from the squamæ on their surfaces, they appear red and irritable, forming rounded spots or patches, from two to four or five lines across; and are slightly prominent, and of a brownish red hue. These patches occasionally heal, like those of lepra, from the centre to the circumference; and in this case they present slight depressions in the centres, and acquire a yellowish dusky tint. The scales formed on their surface are reproduced as soon as they are removed. As they decline, the patches often are transformed into segments or arcs of circles; and when quite removed the skin presents small stains of a grayish brown or yellowish hue in the spots occupied by them.

9. This variety is seldom accompanied with much pruritus, unless when the body is heated by exercise, or by stimulating or heating food and drink. It may be confined to the hairy scalp, face, trunk, or extremities; or be disseminated over these regions, appearing either at once upon all of them, or upon each in succession. The patches or spots are generally irregularly disseminated, being crowded in one situation, and thinly scattered in others; but they are more numerous in the line of extension in the extremities than in that of flexion. Guttated psoriasis appears most frequently in spring and autumn, and often disappears in summer or in winter. It may thus recur for many successive years. It is not infrequent in children, and is more quickly evolved in them, often with slight fever. It is more prevalent in adults than in children and old persons. It often presents characters intermediate between psoriasis and lepra. It sometimes coexists with one of the other forms of psoriasis, and I have seen it associated with pityriasis. When it affects the fingers, it often implicates the nails.

10. ii. PSORIASIS DIFFUSA. —SYNON. *Psoriasis confusus*, Rayer. *Lepidosis psoriasis*, Good. *Lepriasis diffusa*, Dendy. *Spreading dry scall*; *scally tetter*.—a. In this variety the patches are of large size, of variable extent, and irregular form. They are developed either by a number of small elevations, like the preceding variety, which run together and form one continuous patch, or by a papular roughness of a patch of the epidermis and congestion of the subjacent dermis, or by several patches, which speedily increase in size and coalesce. In each of these modes the patches may require two or three weeks to be fully formed. The surface of each is usually then of a dull red colour, rough, and

slightly elevated above the surrounding skin, intersected by furrows which correspond with those of the epidermis, and often fissured by several deep chaps. The patches are covered by numerous thin epidermic scales, the removal of which is rarely followed by any fluid exudation. The eruption often assumes the characters of the guttated or discrete variety over different parts of the body, and the diffused form around the joints and extremities.

11. Diffuse psoriasis may occur in a single patch, of various sizes, or in several and upon any part of the body; but most frequently on the fore-arm, or about the elbow and wrist, and, unlike lepra, chiefly the fleshy parts of the limbs. Its duration is always chronic; even its mildest states may continue for weeks or months, and the severest forms may remain for months or years.

12. Diffuse psoriasis, when extensive, is often preceded by symptoms of constitutional disorder; especially indigestion, costiveness, languor, and debility, which frequently subside as the eruption is developed, but which often recur. The eruption is generally attended by slight pruritus, and by pain and tenderness after the removal of the scales, or when the patches are fissured or chapped. It occurs chiefly in adults and the middle-aged.

13. b. This variety has, in rare instances, assumed a *gyrated form*—*Psoriasis gyrata*, or that of narrow bands, or curved or tortuous lines. Biett describes it as long, narrow, tortuous stripes, resembling worms; and sometimes bending into rings, occurring generally on the back, or trunk of the body. These stripes are covered, by very delicate epidermic scales, which exfoliate, and are reproduced as in the other forms of this variety. They are attended by a slight pruritus, and but little inconvenience. In very rare cases the eruption assumes an *annular form*, especially about the neck and face of delicate persons, and is very slight.

14. c. In children, diffuse psoriasis is occasionally seen in a sub-acute form—*Psoriasis infantilis*, WILLAN. It appears from two or three months to two or three years of age. It is more acute, is attended by more pruritus and smarting, and is much more rapid in its progress than in adults. The surface of the patches, which are often large, is intersected by numerous fissures or chaps, and often excoriated by friction; the excoriations exuding an ichorous fluid, which dries into hard scabs of considerable size. In infants and children this eruption may be attended by phlyzacious pustules, by a morbid secretion from the nostrils, by loss of the hair of the eyebrows and the eyelashes when the forehead is affected, and by hardened elevations of a reddish hue.

15. iii. PSORIASIS INVETERATA.—SYNON. *Lepriasis candida*, Good. *Dartre Squameuse lichenoïde*, Alibert. *Lepriasis inveterata*, Dendy. *Inveterate dry scall*.—When either discrete or confluent psoriasis has continued months, or years, or sometimes after the more inflammatory form of pityriasis has persisted long, especially when the eruption is hereditary, or occurs at an advanced age, or attacks a debilitated or shattered constitution, or is consequent upon protracted functional disorder of the digestive organs, then the eruption assumes the

form thus named. It may be regarded as an aggravated form of psoriasis diffusa. Inveterate psoriasis usually extends over a large surface, occupying the most of the limbs, and of the trunk; the face, the palms of the hands, and the soles of the feet being free. The skin is thickened, congested, hot, dry, and harsh. It is stiff, fissured by deep cracks, and covered by epidermic scales and scabs, which are thrown off in great abundance. Pruritus is very troublesome in this variety, and is increased by the heat of bed and by a heating regimen. The thickening of the integuments restrains the motions of the limbs and flexions of the joints. When the surface is abraded or excoriated by friction or otherwise, a fluid exudes which concretes into scabs. When this eruption affects the scalp, the scales collect in numbers; and when they are removed, an ichorous fetid exudation takes place from the reddened surface. When it extends to the hands, the nails are remarkably affected; but in some cases I have observed the affection of the nails without the fingers being otherwise implicated, and have imputed the disease of the nails to the infection of the fluid exuded from the surface scratched by them. The constitutional disturbance may be but slight even in the severest cases, particularly in respect of febrile symptoms. But the functions of the stomach, liver, and bowels are often languid and torpid, and the several depurating actions impaired. The duration of this variety is always prolonged and indeterminate. In old persons it continues for the rest of life.

16. LOCAL STATES OF PSORIASIS.—(a) Psoriasis may occur primarily on the *hairy scalp*; but it is more frequently consequent upon the eruption in some other part, or upon neglected pityriasis. It is oftener seen in the *distinct* form; much more rarely in the *confluent*. In rare instances it has extended over nearly all the scalp, extending to the forehead in a line parallel with that of the hair. The inflammation sometimes attacks the bulbs of the hair, which become detached in the patches affected.

17. (b) *The face* is rarely affected alone, the eruption generally appearing also in some other part. The patches on the face are usually red and furfuraceous, the scales being light and thin. On the *eyebrows* and *eyelids* it appears, as everywhere else, by the formation of papulæ. The eyelids become stiff, and slightly fissured or chapped, and these changes are followed in children by the loss of the ciliæ and the hair of the eyebrows. It rarely affects the *lips*, as true psoriasis, but generally in a form that more strictly belongs to *pityriasis*.

18. (c) *Psoriasis genitalium* is not infrequent, and either the *prepuce*, or the *scrotum*, or the *labia majora vulvæ* may be the seat of the eruption. In either of these situations it presents the characters already described. It seldom appears in any of these primarily, but generally in connexion with its occurrence in other situations. It may, however, be consequent upon prurigo or pruritus of these parts. In the *prepuce* this eruption is often obstinate and severe, and is sometimes attended by thickening, painful exudations of blood and fissures, and phymosis. Psoriasis in this situation may be associated with psoriasis of the *scrotum*, which is often most obstinate, and assumes the invet-

erate form, or with *psoriasis palmaris*. As respects the characters of the eruption, there are no differences produced by these localities. But swellings of the inguinal glands are often caused by the appearance of the eruption in these situations; and care should be taken not to confound it with venereal affections.

19. (d) *Palmar psoriasis*—*Psoriasis palmaris*—may be either distinct or confluent; but in either form the elevations are generally broad, of a pale reddish hue, and the seat of much heat and itching. If the elevations are numerous they become painful, and interfere with the patient's occupations. In the confluent form the palm of the hand swells, and presents a uniform brownish red colour. As the eruption becomes more chronic, the heat and itching are less troublesome, the cuticle covering the elevations grows thicker, acquires a yellowish hue, dries up and becomes friable, and at last of a dead white on the surface of the patches. The epidermis then cracks, and is detached either spontaneously or by the nails of the patient, and leaves a new epidermis, through which the corion appears red and vascular. The epidermis surrounding the diseased patch also undergoes a change, being thicker than usual, of a dirty yellow tint, and subsequently becoming dry or mealy on the surface. It finally exfoliates irregularly, at first adjoining the older patches, and then in the flexures of the joints and natural folds of the palm. The desquamation is always *irregular*, and very different in appearance from that of the next variety, the *psoriasis palmaris centrifuga*; but, like it, and even more constantly, is attended by linear fissures, which penetrate to the quick in the lines of the palms, and by smaller cracks or fissures which extend less deeply.

20. (e) *Centrifugal palmar psoriasis* is less common than the preceding. It begins in the palm by a single elevated spot, solid, and of small size, upon which a small white scale is formed. Around this elevation a series of red eccentric circles are produced, each in succession, and are covered by epidermic scales, which exfoliate. As these circles appear, each successive one is more eccentric, until the whole palm is implicated, and each undergoes desquamation. Squamous patches also appear on the palmar aspects of the fingers. The palmar integument is reddish where the exfoliation of the scales has taken place, is thickened, and fissured by numerous claps, some of which, upon opening the hand, which is painful and stiff, sometimes exude a little blood.

21. Both these forms of palmar psoriasis are of long duration, they seldom continuing for a shorter time than several months, and often persisting for years. They often decline in summer and autumn, and are exacerbated in winter and spring, for a number of years. Palmar psoriasis is sometimes complicated with *psoriasis genitalium* in either sex. A modification of it sometimes affects, although much less frequently, the soles of the feet—*psoriasis plantaris*; but the severity of the symptoms is less in this situation, owing probably to the structure of the plantar integument, and to the protective coverings of the part. Fissures in this situation are much less apt to occur, and are smaller when they occur.

22. (f) A variety of psoriasis diffusa occa-

sionally affects the backs of the hands, and is called *grocers' itch*, because it is often seen in persons engaged in this trade; but it also often attacks bakers, laundresses, and others. It begins with two or three squamous elevations, which often spread until the whole back of the hand is covered. The integument at length presents numerous dry and painful fissures over or near the wrist and the articulations of the metacarpal bones and first phalanges of the fingers. This variety is distinguished from confluent and chronic *lichen* of this part by the circumstance of the latter always commencing in an eruption of small papulæ.

23. (g) *Psoriasis of the Nails*—*Psoriasis Unguium*.—When the disease affects either the upper or the lower extremities, the nails are often attacked, even although neither the fingers nor the toes may be affected. But the affection of the nails never occurs without some other part being attacked. It is most frequently associated with *psoriasis guttata* of the hands or arms. The nails, when diseased, become yellowish or tawny; thickened and irregular in their structure; rough, ragged, and brittle, and often bent over the ends of the fingers. A cheesy-like matter is sometimes formed at the roots of the nails, or between the roots and the matrix, as at the extremity of the papillary surface, these parts sometimes becoming unusually vascular, and giving rise to thickening, &c.

24. (h) *Psoriasis* is often complicated with visceral disorder, as already noticed, and sometimes with *lepra* or  *pityriasis*. It has also been seen associated, especially in children, with *eczema impetiginodes*, vesicles and purulent points appearing amid the thin squamæ covering the patches of *psoriasis*. At a later period these patches become excoriated, and form thin, lamellar, yellowish scabs like those of *eczema*. This association is not infrequent in children during the period of teething, and occasionally at a more advanced period.

25. iv. PSORIASIS LEPRÆFORMIS. — SYNON. *Lepra*; *Lepriasis*. *Lepra Græcorum*, Auct. *Lepra vulgaris*, Willan. *Psoriasis circumnatus*; *Lepidosis lepriasis*, Good. *Lepriasis annulata*, Dendy. *Psoriasis orbicularis*; *Dartre Squameuse arrondie*, Alibert. *Scaly leprosy*; *Greek leprosy*.—This chronic squamous eruption is characterized chiefly by its consisting of circular and slightly-raised patches, which are speedily covered by thin, semi-transparent, epidermic scales, the patches being prominent at their edges, and somewhat depressed in their centres, and the scales being thrown off and replaced by successive formations. *Lepra* is occasionally confined to the knees and elbows, and it generally appears first in these situations, or, rather, immediately below them. In most cases it affects both legs or both arms at the same time. It is apt to extend by the successive formation of new scaly patches along the arms and thighs, to the breast and shoulders, and to the lumbar and lateral regions of the abdomen. The patches are sometimes more numerous, large, and prominent on the lower part of the trunk. The disease rarely extends to the hands or hairy scalp. The patches which appear on the head are usually of a small size. They are seen near the outer angles of the orbits, whence they spread along the eyebrows to the forehead and temples. When *lepra* extends

to the hands or fingers, the nails and the matrices of the nails are often affected in a similar manner to that described above (§ 23). Everywhere the patches are apt to coalesce by their corresponding edges; but the originally orbicular form of the aggregate patches is partially preserved in the arcs of circles which are seen in the circumference.

26. *A. Lepra vulgaris* commences with small, smooth, solid elevations of a dull red hue, around which numbers of other reddish, prominent spots, about a line in diameter, are evolved. The surface of the elevations become covered in two or three days with thin whitish scales. In four or five days the elevations spread, having thrown off the small spangle-like scale from their summits, and are attended by a sense of heat, tingling, or pruritus. They then enlarge rapidly by the extension of their circumference, which is raised and red; while the centres become depressed and paler than the margins. As the scales exfoliate others are produced, and are of a glistening or opalescent, or of a pearl-gray or pale yellow tint. The squamæ are not evenly spread over the surface of the patches, and they are detached partially and irregularly. After their fall, the skin which they covered looks red, shining, and somewhat raised. They are superposed, especially in the circumference of the patches, and thus become thicker and thicker, so as to form prominent layers. Even when small, the patches are never covered by a single scale. When they are recent, the corion does not present lines corresponding to those of the cuticle, but when they are older such lines are observed, and are often increased to wrinkles, which correspond with small indentations or ridges in the inner surfaces of the scales. However detached from the inflamed surface, a fresh formation of scales takes place.

27. The cure of the orbicular patches of *lepra* begins in the centres, and extends to the circumference. After the detachment of the squamæ the skin acquires, when they are not renewed, a grayish tint, with a shade of yellow. At a later period, the ring bounding the patches is narrowed progressively from within outward; the circle at last is broken in one or more places, and the spot ultimately disappears entirely. (RAYER.)

28. *Lepra* is seldom attended by any febrile disturbance, or other disorder than impaired digestion, assimilation, and excretion. The appetite is usually good, and generally greater than the powers of digestion. It occasions no farther inconvenience than slight itching upon getting into bed, or upon changes of temperature. But when the patches are extensive or numerous, or when the inflammation of them is increased by a heating regimen, the patient feels so much burning or stinging pruritus as often to disturb repose. When the patches surround the joints they cause stiffness, and occasionally are attended by small painful fissures. The disease is always of considerable duration; it often continues for years, sometimes for life. I am now attending a lady who has been afflicted with it extensively for upward of forty years, although she has always had the advantage of the best medical advice.

29. *B.* The variety denominated *Lepra alphoides* by WILLAN is merely a milder form

than the preceding, the squamous patches remaining of small size, and seldom exceeding a few lines in diameter. The spots increase slowly, are slightly prominent, and rarely run into one another. They form almost exclusively on the joints and extremities, and differ from the patches of *lepra vulgaris* chiefly in the small size and whiteness of the scales which are formed. They are commonly met with in children and delicate persons, and are not easily distinguished from *psoriasis guttata*. Several other modifications are sometimes observed in the form, disposition, and extension of the patches, depending upon their seat and the constitution of the patient; but these are too numerous to describe. Some of them so closely resemble *psoriasis* as hardly to be distinguished from it. When this variety affects the scalp or pubic region, it often occasions much pruritus or inconvenience; but it rarely affects these situations exclusively. The squamæ in these situations are generally yellow and furfuraceous, and are without the glistening micaceous hue they present on the knees or elbows.

30. *C. Lepra nigricans* is a comparatively rare form of *lepra*, and is met with only in cachectic and broken-down constitutions. The form and distribution of the patches are the same as described; but the patches are not so large, and are generally without the central depression. Instead of being of dull red or rose-colour, they are of a livid or bluish brown hue. Mr. E. WILSON states that the scales are so thin as to allow the lividity of the surface to be seen through them, are easily detached, and leave behind a tender and frequently an excoriated surface, from which a morbid serous fluid, often mixed with blood, is poured out. This exudation hardens into an irregular and friable crust. This variety is particularly annoying when it affects the scalp. It occurs chiefly in persons whose occupations expose them to the vicissitudes of the weather, and to a precarious diet, with fatigue and watching, and excesses in spirituous liquors, &c.

31. V. PSORIASIS ET LEPRIASIS SYPHILITICA.—SYNON. *Squamæ Syphiliticæ*.—*Lepra Syphilitica*, *Psoriasis Syphilitica*, Willan. *Syphilitide pustuleuse*, Alibert. *Syphilides Squamæuses*, Rayer. *Lepriasis Syphilitica*, Dendy. *Scaly Syphilis*.—Secondary syphilis assumes every species and variety of cutaneous eruption; and no species more frequently than *psoriasis* and *lepriasis* in all their forms. Mr. DENDY states, that the most common form of scaly syphilis is that of irregularly scattered spots, which, however, become occasionally confluent, and sometimes three or four forms or distributions of scale are seen in the same subject, viz.: *foliaceous laminae* on the scalp, *guttated* and *diffused psoriasis* with indurated scales on parts subject to pressure, heat, or friction, as the palms, soles, axillæ, serotum, and labia vulvæ; *psoriasis lepraformis*, or *lepra*, on the breast, abdomen, and thighs; and very rarely an extensive *psoriasis diffusa*, as a syphilitic eruption.

32. *A. Psoriasis guttata syphilitica* commences in a copper-coloured, livid, or violet spot, at first extremely small, usually becoming from six to eight lines in diameter, and, when extending to the scalp, assuming a greenish olive or dull yellowish hue. The spot is flatter, softer, and

smoother than the incipient papulæ of common *psoriasis*, and less squamous, having little or no defined edge; or it may be sometimes larger or redder, more defined, and less squamous. The spots or patches are often more ovoid than circular; the diseased cuticle on their surface is usually more furfuraceous, still adhering tenaciously, and it is of a dull violet or yellowish hue, rather than white. When the scales are detached they are of dirty pearl gray, the livid colour being imparted by the subjacent tissue. After one or two exfoliations the squamous character often diminishes, and, under mercurial influence, disappears in three or four months. If a syphilitic treatment fail, they will degenerate, the squamous character changing to that of a blotch, or even to superficial ulceration. In some cases, Mr. DENDY remarks, that in the centre of the scale a sort of pustular or ulcerated character is observable, even in an early stage, very similar to the moist crusts of *eczema*. This is never seen in the common forms of the non-syphilitic eruption.

33. *B.* Another form of scaly syphilis is that of a *dusky or brownish, livid, circular spot*, the centre slightly fissured and foliaceous, the cuticle detached, as it were, around the disk, and thus forming a white margin. This form nearly resembles *ecthyma syphilitica*. (See art. *Еcthyma*, § 6.) In both these forms of syphilitic scales, ulceration of the throat is often also observed.

34. *C. The annular syphilitic scale*, or syphilitic *lepra*, is less defined than the common circular *lepriasis*; the margins are slightly raised, the scales are dusky rather than white, and more annular. "In some cases the guttated and annular forms become one elevated, brownish, red mass, here and there spotted with scales."—(DENDY.)

35. *D.* Syphilitic scaly spots usually appear from five to ten weeks after the subsidence of a chancre. "Mr. CARMICHAEL believed it to be the sequence only of that ulcer which was marked by indurated edges—the true Hunterian chancre." Mr. DENDY does not think that it is thus limited, for he has seen it consequent upon primary pustules which had speedily subsided, and both consequent upon and coexistent with almost every primary form of the syphilitic malady.

36. The most common seat of scaly syphilis is on the forehead, "*corona veneris*," and the breast. When, however, the patches speedily arise during acute or often-recurring primary disease, especially in depraved constitutions, they often appear first in the vicinity of the organs of generation, and are then more defined. The character of the patches or spots is, however, much altered by the treatment, especially by external applications.

37. The spots of simple *lepra* are generally larger and rounder than those of syphilitic origin, the latter being much more rarely confluent and united into broad bands and patches than those of the former. Scaly syphilis is, however, much modified by locality. When it is seated in the axilla, or between the toes, it is moist, whitish, and very offensively fetid. Sometimes, also, fissures form, and the cuticle peels rather than drops off. On the scalp it assumes a greenish livid hue. On the palms and soles it is usually guttated. The spots,

however, are not so distinct as in other parts, the cuticle, on being detached, also appearing more horny and yellowish; and in this situation exfoliation is often very protracted. If fissures form, and the feet and hands are subject to much pressure, they become deeply ulcerated. If the matrix of the nails become affected, painful or phagedenic onychia may follow. (DENDY.)

38. *E. Infantile scaly syphilis* is almost invariably marked by *snuffing* from the child's birth. The skin is of a dirty yellow or waxen hue, with numerous brownish pink spots, presenting a sprinkling of a gray or brownish white dust, which is often most abundant on the circumference of these spots. The disease may resemble, also, the livid spots already described, even at a very early age; but more frequently an association of these differently tinted spots are observed on the face and hands.

39. III. DIAGNOSIS.—The differences between the species of scaly eruption have often been exaggerated, or the extreme points of difference have been chiefly adduced and placed in bold relief by most of the writers on diseases of the skin, believing that the enumeration of minute distinctions and the recognition of modifications of the external characters would evince a more intimate knowledge of their nature than a display of their relations, not only with one another, but also with the state of the digestive, the assimilating, and the excreting functions, and of the circulating fluids. The devotion to "specialities," with the view of attracting the public by the presumed advantages of, and by the superior knowledge assumed from, a division of labour, was first manifested in modern times by the writers on skin affections; and, like all others devoted to a single craft, who adopt merely a minute segment of the great circle of medical science for their practices on the public, rather than for its proper cultivation and improvement, they merely partially advance the trivial and the mechanical to the detriment of profound or comprehensive views, and they fail in the recognition of extensive morbid relations. While a few local distinctions or mechanical contrivances are paraded as proofs of a superior acquaintance with the adopted subject, their narrowed powers of mental vision fail to recognise much more important relations and matters, the sources from which the local mischief proceeds, and the varied sympathies which either produce, or are produced by, the object of exclusive adoption and cultivation, a cultivation resembling merely the superficial scraping of the soil by the hands of savage ignorance, not the deep ditching, the draining, and the manuring of applied science. The human microcosm cannot be advantageously studied in one of its parts only, nor can its states, affections, or structural lesions be either understood or remedied by confining our inquiries and our means to a particular or limited locality, even although that locality is the seat of disease. The animal body is one and indivisible, no one part being independent of another—no single system, or organ, or tissue, being disordered or diseased without implicating more or less the functions, and even the organization of several, or even of all the rest. Hence it is that no division of labour which has been adopted in medical practice in ancient times, since the ages of the PHARAOHS, down either to the modern days of

the higher and more regular grades of empiricism, or to the lower degrees of quackery and imposture, has tended to advance medical science or to raise the respectability of our profession. On the contrary, all such divisions, all adoptions of a single member, organ, or viscus for special practice or study, have lowered, in proportion to the degree of division, our science to a craft, and sunk the physician to an empirical practitioner: they may have enriched the charlatan, but they have degraded the profession.

40. Those who have taken the eruptions of the skin under their protection, or the "Dermatologists," as they have dignified themselves, have generally laboured to point out the extreme distinctions which may exist between the several forms or cases of scaly eruption; limiting, however, their distinctions to the form, the size, the tint, and the thickness of a scale; and to the form, size, hue, and condition of the tissue underneath. Their distinctions have been always local, and without reference to the states of the assimilating and depurating functions, and of the circulating fluids and excretions. Even the most important of all local distinctions have been neglected; for they have failed to show whether the scales are an exuberant formation of cuticle—are diseased cuticle hastily formed and as hastily thrown off—or are merely a thin albuminous exudation on the inflamed surface, that becomes altered by the action of the oxygen of the air, and thrown off by the local morbid action and the state of its vital and vascular relations; or in how far various states or appearances of these scales depend upon a morbid cuticular formation, or upon a modified albuminous exudation, upon the production by and upon the skin of an oxidized albumen.

41. *The diagnosis of scaly eruptions* is therefore hardly to be regarded as respects the several forms which they assume, because shades of difference, too slight and too varied, and ever varying, to admit of description, are even more common than more marked distinctions; but it may be entertained as regards other eruptions with which the squamous may be confounded, upon a hasty or imperfect view, and if the history, progress, and morbid relations of the case are not observed. The chief differences which exist between the leprous and other species of psoriasis are, that generally in the former the patches are circular, with raised margins and somewhat depressed centres, the scales being moderately thick and slightly adherent; while in the other species the patches are irregular, not depressed in their centres, and are covered by thinner and more adherent scales. Psoriasis guttata, however, very nearly approaches to the leprous species, especially to the alphoid variety, the distinctions now stated existing in some respects, and the patches of the latter being generally of larger size. Pityriasis may be confounded with psoriasis; indeed, it is but slightly different, either in local characters or in pathological relations, from the several species of psoriasis; so that pityriasis, psoriasis, and lepra may be justly viewed as species of one genus. The distinction between pityriasis and the other species consists chiefly in the more superficial affection of the skin in the former, and in the smaller size and more

furfuraceous character of the scales. The integuments, moreover, are often chapped or fissured in the latter, and but rarely in the former. *Lichen circumscriptus*, with its annular clusters of papulæ, fading towards the centre, may sometimes be mistaken for leprous psoriasis, especially in process of cure; but the existence of the former is shown by the presence of marginal papulæ; whereas in the latter the inflamed surface, denuded of its scales, is smooth and devoid of papulæ. *Tinea annularis*, or *ring-worm*, at certain periods of its progress, either at the commencement or the end, when the crusts fall off and leave behind red annular-shaped patches, may be mistaken for lepra of the scalp, especially if there are patches on other parts of the body. But the one is as rarely seen on the body as the other is on the scalp; besides, the favous pustules of the former will indicate its nature. It should be recollected that several varieties of squamous eruption may exist in the same case, and that it may be associated with other eruptions, as with tinea.

42. IV. PROGNOSIS.—The several species of this eruption are more or less obstinate. The prognosis depends much upon the condition of the patient, and the duration, species, and state of the eruption. Even the mildest forms are apt to return after having disappeared, upon the recurrence of the causes, regimen, and diet especially, which first occasioned it. *Psoriasis guttata*, although not a severe form, is yet very obstinate, and is apt to return after disappearing. The *diffused variety* is still more obstinate, especially in debilitated, old, or cachectic persons; and the *inveterate form* often resists all treatment, particularly in those unfavourable circumstances. The same prognosis applies to the different forms of the *leprous species*. It is rarely attended by danger, and in young subjects it is often cured; but in adults and aged persons it is always very rebellious, and often incurable, although treatment may restrain its progress and palliate most of the more annoying symptoms. The existence of an hereditary predisposition to any of the species of scaly eruption militates strongly against a perfect cure, especially in patients advanced in life; for, even if almost or altogether removed, it seldom fails to return. The *syphilitic scaly eruptions*, when not associated with serious disease of the throat, or of the periosteum, or of the joints or bones, and not advanced to extensive ulceration, will generally be removed by appropriate treatment, unless the disease be developed in the scrofulous diathesis, or is connected with an abuse of mercury, when a less favourable opinion of the result, as respects the constitution and vital organs, should be entertained.

43. V. THE PATHOLOGY OF SCALY ERUPTIONS has been imperfectly, if, indeed, at all considered. These eruptions have been viewed as altogether local, and their obvious dependence upon the state of the circulating fluids most unaccountably overlooked. Many years ago (in 1822) my attention was attracted to the state of the blood by a case of psoriasis, for which I had prescribed venesection, and found the serum remarkably milky or whitish-coloured. Since then other cases have furnished evidence of a superabundance of insufficiently assimilated chyle, of albumen, and sometimes of fatty matter in the blood of patients severely affected

with either of these eruptions. It is very obvious that impaired function of the liver and digestive canal, as well as of other assimilating organs, will be followed by the presence, if not by the superabundance of imperfectly assimilated chyle, and chyle-globules in the circulation; and that equally impaired excreting function will occasion a state of excrementitious plethora; the imperfectly assimilated and the effete materials thus accumulated in the blood exciting and perpetuating irritation of the capillary circulation of one or other of those emunctories whose office it is to remove these materials from the circulation. Irritation of the cutaneous surface having gone on to inflammation of a slow and chronic form, and the blood abounding with albumen, a state of capillary action and a material are thereby furnished for the formation of the scales which are so abundantly produced on the inflamed surface, and which is rarely, excepting at the commencement of the eruption, an altered state of the cuticle, and a morbid reproduction of it, but an exudation of albuminous lymph from the diseased capillaries that is modified by the state of the blood and the local action, and by the oxygen of the air, so as to form the several varieties of squamæ observed in this genus of eruption. This view of the nature of squamous eruptions shows the impropriety of employing local or external means solely or chiefly in the treatment, and of thereby shutting up a safety-valve in the economy opened by the course of functional disorders; and it accounts for the occasional superposition of serious visceral disease upon the suppression of the cutaneous eruption. It also suggests the use for these and similar eruptions of such means as shall most effectually remove the disorders of the digestive, of the assimilating, and of the excreting functions, upon which these eruptions are chiefly dependent, and the impropriety of prescribing external means otherwise than as aids to internal and constitutional treatment.

44. VI. TREATMENT.—The circumstances which require especial attention, before the intentions of cure are determined upon in each case of scaly eruption, are the following: 1st. The habit of body, diathesis, age, and employment of the patient. 2d. The indications of disorder of the digestive, of the assimilative, and of the depurative functions in connexion with nervous and vital power. 3d. The duration and character of the eruption, the causes in which it originated or tend to perpetuate it. These last circumstances should be viewed in connexion with the previous diet, mode of living, &c., commonly adopted by the patient. These particulars being ascertained, the *states* of those suffering any form of the eruption may be arranged as follows, as furnishing the chief bases for therapeutical intentions: *First*, as regards *habit of body*, &c., indications of *plethora*, or of *anæmia*, and of *digestive* and *excreting derangement* ought to be carefully observed, and the several associations of these states. *Second*, as respects the *duration* and *appearances of the eruption*, the amount and character of the *inflammation*, and the *discrete or confluent*, or *syphilitic* form of the eruption ought to be noted; and, *Third*, the state of *vascular action*, generally and locally, and of *constitutional power*. These data having been obtained as accurately as pos-

sible, and with due reference to the states of the blood and of the functions of waste and supply, the intentions are, 1st. To remove whatever disorder may exist in the quantity or quality of the blood, and in vascular action; 2d. To restore the digestive and depurative functions, as being subsidiary to the first indication; and, 3d. To correct the morbid action on the skin by rational local means.

45. Viewing the cure of scaly eruptions as being thus dependent, at all times during treatment, upon a due exercise of the several vital actions, especially those of digestion and depuration, and upon a sufficient, but not an exuberant supply of wholesome food, the application of these indications of cure should be accompanied with strict attention to *diet* and *regimen*, as noticed in the sequel, and with a careful avoidance of the several predisposing and exciting causes (§ 3, *et seq.*).

46. A. If the patient be *plethoric, strong, or young*, and the eruption copious, red, and not of long duration, and more especially if the pulse present sufficient tone, local and general action not being impaired or asthenic, then *blood-letting*, according to the peculiarities of the case, should unhesitatingly be prescribed; and in healthy, dry, and country localities, if the patient has lived fully or richly, it may be repeated, according to the effect produced by the first. After bleeding, an active antimonial *emetic* ought to be given, and its operation freely promoted. When the stomach is quieted, the bowels, and, through them, the liver, should be freely evacuated by chologogue and stomachic *purgatives*. At first, and on several occasions afterward, a full dose of calomel, with some purgative, ought to be prescribed, and its free operation promoted by an *enema* containing spirits of turpentine and castor oil, or some other cathartic. These should be repeated according to circumstances, but sufficiently often to procure not only an entire evacuation of all crudities and accumulations, but also an increased discharge of all secretions and excretions from the digestive canal, and, through the medium of it, all effete or injurious materials from the blood.

47. B. When the patient presents no indications of *vascular plethora* or of increased action, and the patches are not very irritable or much inflamed, then blood-letting may be omitted, or a small blood-letting only prescribed. In the metropolis and large manufacturing towns, vascular fulness and excitement are not generally such as require more than a small, or a local bleeding only; and not infrequently a state of *anæmia*, requiring opposite means to this, is met with in connexion with scaly eruptions.—*a.* For the former of these cases *emetics* and *purgatives* are indispensable, and for the latter they are not the less so; but the purgatives should be either conjoined with *chalybeates* or vegetable *tonics*, or alternated with them, so as to improve the powers of digestion and assimilation simultaneously with the evacuation of injurious matters. MM. CAZENAVE and SCHEDEL remark, that “when the patient is young and vigorous, and the disease pursues a rapid course, the skin being hot and inflamed, and the pulse full and quick, then venesection, simple baths, diluents, strict regimen, and quiet are necessary.” To these, however, I would add emetics

and purgatives, as above advised (§ 46). In old and feeble persons, or in constitutions broken down by privation or excesses, in whom there is either but little inflammation, or inflammation of an asthenic or cachectic character, a course of tonics should be directed, and either alternated with or followed by purgatives and other energetic measures, according to the peculiarities of the case.

48. M. BIETT, although he says nothing as to exhibition of an emetic either at the commencement or in the course of treatment, strongly recommends a purgative course, especially when the disease is recent, and the patient young or robust. He advises calomel every morning, fasting, in four-grain doses, either alone or with the same quantity of jalap. Sometimes sulphate of soda or sulphate of magnesia, taken in a considerable quantity of a bitter infusion, is very beneficial; and occasionally a more active purgative, as colocynth, scammony, gamboge, &c., may be employed. The choice should be guided by the conditions of the patient and of the eruption, and by the effects of the medicine previously employed. M. BIETT advises the calomel and the other purgatives to be continued daily for several weeks—for two months—if they do not produce a complete cure within that time. If salivation or other specific effects of the calomel appear, this substance may be omitted or the dose reduced; but this effect would seldom appear, and will not delay the cure. It is often necessary, or even advantageous, to suspend the treatment for three or four days, and then renew it. I have generally preferred to combine the calomel with rhubarb, and sometimes also with magnesia; or to give the calomel alone, much less frequently, and soon afterward a full dose of sulphur and magnesia; or the pilula hydrarg., chloridi comp. with soap and extract of colchicum at bedtime, and sulphur with magnesia in the morning. When sulphur is prescribed with magnesia, an aromatic powder may be added, and the medicine continued once or twice daily, so as to keep up a free evacuation from the bowels for several weeks, the tepid or vapour bath, or other external means about to be stated being also employed in aid of them.

49. *b.* The *tincture of cantharides*, administered in any mucilaginous diluent in doses gradually increased from five to fifteen or twenty or thirty drops for a dose, was much praised by BIETT, and, as M. RAYER observes, occasionally causes the rapid disappearance of the eruption, especially of the leprous form, when not severe, or only recent and limited in extent. But if taken in larger doses, it may, although it relieves or removes the eruption, excite inflammation of the digestive or urinary organs, or of both.

50. *c.* The *arsenical preparations*, especially FOWLER'S solution, has proved very efficacious in scaly eruptions, and I have found it more certain in its effects than almost any other single medicine. But the good effects have seldom been permanent, or even so progressive as to effect a cure in the more severe cases, unless the diet be carefully regulated. There is often, also, a liability to a recurrence of the eruption after it has been removed by too large or too frequent doses of any arsenical preparation; but this liability exists in most cases, and is to be met only by a most careful avoid-

ance of the exciting causes. MM. CAZENAVE and SCHEDEL state, that as psoriasis is often more obstinate than lepra, the remedies, especially arsenic, should be pushed farther for the former affection; and that a permanent cure, without any dangerous results, may be obtained by the judicious administration of arsenical preparations. M. BIETT also entertains a similar opinion. These preparations should not be given oftener than twice daily, and the dose ought not to be larger than three drops at first, nor increased beyond ten or twelve. In many cases they should be given after a full meal, especially when the dose is large, and when the course is protracted; and, unless the dose is very small, an intermission in the use of the medicine for three or four days should be directed. The following is the mode in which I have usually prescribed arsenic for the cure of psoriasis:

No. 327. R. *Liquoris Potassæ Arsenitis*, ℥iij. ad ℥v.; *Liquoris Potassæ*, ℥xv. ad ℥xxxv.; *Extr. Fluidi særæ comp.*, ʒj.; *Tinct. Aurantii*, ʒj. *Infusi Gentianæ Comp.*, ʒx. *Aq. Cinnamom.*, ʒss. M. *Fiat Haustus bis quotidie sumendus.*

51. I believe that large or too frequent doses of arsenical medicines are not only more injurious to the constitution, but actually much less beneficial, as regards the eruption, than either very small or very moderate doses. This circumstance will account for the not very favourable opinion expressed by Dr. A. T. THOMSON respecting them. He observes, "That notwithstanding the powerful influence of arsenic in psoriasis inveterata, I have met with cases which resisted it, even when administered in the largest doses. In some cases erysipelas has accompanied the use of the arsenical solution, in which case the remedy should be suspended until the erysipelas be removed, and afterward renewed in smaller doses." (P. 67.)

52. *d.* Dr. THOMSON adds, "That the medicine on which the greatest confidence may be placed in psoriasis is the *liquor potassæ*." He commences with thirty drops in two fluid ounces of the bitter almond emulsion twice a day, and gradually increases the dose of the solution to eighty or even one hundred drops. If the patient be delicate, the infusion of yellow cinchona or of cascarrilla is substituted for the almond emulsion; and he has found the *hydrargyrum eum creta* in doses of six or eight grains, at bedtime, a useful aid to this practice. I have employed a similar treatment, but could rarely succeed in getting the patient to take so large doses of the solution as he advises; indeed, I view them as injurious to the digestive organs and kidneys. I have seen marked advantage derived from it conjoined with the *iodide of potassium*, and taken either in a bitter infusion or in one of the decoctions advised for this eruption.

53. *c.* The *bi-chloride of mercury*, taken in the decoction of cinchona, or of sarsaparilla, or of dulcainara, has been also recommended, and is beneficial in slight or recent cases; but has failed in every case of inveterate or of protracted leprous psoriasis in which I have tried it. Dr. A. T. THOMSON states, that he has found the combination of iodine with mercury the most successful of any mercurial preparation for this disease. "The *biniodide*, in doses of a sixth to a fourth of a grain, exerts almost a

specific influence upon the morbid state of the skin; and when given at the same time as the *iodide of arsenic*, and aided by blood-letting, it has rarely failed in curing the most inveterate cases." As the acrimony of the preparation has disturbed the alimentary canal, he has usually combined it either with opium or with eonium, carefully avoiding pyalism. As, however, he has usually combined the *biniodide of mercury* with the *iodide of arsenic*, it is difficult to determine what share each may have had in the cure. He prefers this preparation of arsenic to the *liquor arsenicalis*. The dose of it, at first, ought not to exceed one tenth of a grain; and in no instance should it be carried beyond one third of a grain. "Its obvious effects are quickness and hardness of pulse, with slight puffiness of the lower eyelids; but generally, before these symptoms display themselves, the disease has begun to yield. The symptoms which indicate a necessity for reducing the dose are, heat of the mouth and fauces, anxiety at the præcordia, pain at the epigastrium, or griping. If, besides these, there is tension, with stiffness around the eyes, erythema of the face, thirst, white tongue, the edges and tip of a florid red hue, and a quick pulse, the medicine should be suspended for some days. If nausea, cough, vertigo, or salivation supervene, it should be left off altogether. The employment of any arsenical preparation is inadmissible, if it cause an uneasy sensation in the chest from the first."

54. The reason of the failure of arsenic in the cure of leprous and inveterate psoriasis is, in many cases, the large or too frequent doses in which it has been prescribed; the poisonous effects of the arsenic being thereby produced before sufficient time is afforded for the development of the alterative operation of the mineral. Most writers who have depended chiefly on arsenic for the cure of sealy eruptions have advised small or moderate doses, and a protracted course of it. GIRDLESTONE, BIETT, RAYER, WILLAN, BATEMAN, and ERICHSEN advise from two to three drops twice a day, up to seven or eight, this dose not to be exceeded, and the course to be persevered in, if none of the injurious symptoms just noticed be occasioned by it.

55. *f.* Recently, a preparation of arsenic, iodine, and mercury has been strongly recommended for the most obstinate and inveterate cutaneous eruptions by Mr. DONOVAN, under the name of the "*Liquor Arsenici et Hydrargyri Iodidi*." The composition of this solution is as follows: Water, one drachm; arsenious acid, one eighth of a grain; peroxide of mercury, one fourth of a grain; iodine, as hydriodic acid, about three fourths of a grain. Twenty minims, three times a day, have been considered as a proper dose with which to commence a course of it, and forty minims, thrice daily, as the largest dose. I have prescribed this solution in many cases; but I consider the dose here advised as very much too large. If the tongue be at all foul or loaded, an emetic, followed by two or three doses of calomel and rhubarb, or jalap, ought to precede a course of it; and at first, from five to ten minims, twice or thrice daily, and very gradually increased to twenty or thirty, at the utmost, will be sufficient. This solution is most serviceable when the liver is

torpid or loaded, and in the strumous diathesis. It, as well as the biniodide of mercury, is very efficacious in the syphilitic scaly eruptions. Mr. DENDY recommends the occasional use of the warm nitro-muriatic foot-bath during the course of this solution.

56. As to the use of arsenical preparations in psoriasis and lepra, Mr. ERICHSEN very justly observes, that they should not be given until the disease had assumed a chronic or inactive character. As long as there is inflammatory redness, heat, or irritation of the patches, they ought not to be employed, as the irritation of the arsenic will augment these symptoms. Besides, during the earlier periods of the eruption, a cure may be effected by the antiphlogistic and other means I have above advised, especially by depletions, emetics, and purgatives, with strict attention to diet and regimen. It is only, therefore, in very indolent, or extensive squamous diseases, and after other remedies have failed, that any of the arsenical preparations should be prescribed; and in all circumstances they ought to be given cautiously, and their effects closely observed; for, if prescribed too largely, or too long, they may injure the constitution much more than the continuance of the eruption, which in many circumstances admits of palliation merely, and not of complete cure.

57. *g.* There are various other medicines that have been prescribed, internally, for the scaly eruptions. The chief of these are, the decoctions of *dulcamara*, of *guaiacum*, of *meze-reon*, of *elm-bark*, the infusions of *nettles*, of *marsh rosemary*, the decoctions of *sarsaparilla*, *sulphur*, and the *sulphurets*, or the milk of sulphur conjoined with magnesia, or with either of the alkaline carbonates, and the *æthiop's* mineral and other preparations of *antimony*. Either of these infusions or decoctions may be made the vehicles for the administration of other more active agents, as the liquor potassæ, with or without the iodide of potassium, the liquor iodidi arsenici et hydarargyri, the liquor hydrarg. bichloridi, &c. In some obstinate cases of psoriasis, after morbid secretions and excretions have been evacuated, I have lately resorted to the use of *spirit of turpentine*, internally and externally, prescribing this substance either alone or with oleum ricini, in doses of half a drachm, or of one drachm, twice or thrice daily, and, after two or three days, the occasional application of an epithem, or embrocation of this spirit over the part chiefly affected. The turpentine ought to be discontinued as soon as it irritates the kidneys, but persisted in if it acts gently on the bowels. It will be taken with little inconvenience on the surface of a little milk or coffee. I have occasionally prescribed *tar-water*, internally as well as externally. It will be found a medicine of considerable power in this and other cachectic disorders, if appropriately employed. *Pitch*, *tar*, and the *turpentine*s have been recommended internally and externally for squamous diseases, and generally in the form of pill when administered internally, tar and the turpentine being rendered more or less consistent by means of magnesia. They are sometimes of service; but they often, in this form, pass into the large bowels undissolved, become excrementitious, and hence have little effect.

[Dr. EMERY, of the Hospital St. Louis, had his attention turned to the investigation of the different products of tar as remedial agents in the treatment of skin diseases, on account of the successful results he obtained from the use of tar, and because of the unpleasant odour it gave forth. Various preparations were had recourse to, the most valuable of which proved to be the concrete naphthaline, which Dr. EMERY tried in fourteen cases. In two cases, one of psoriasis gyrata, and the other lepra vulgaris, it failed in effecting any good; in the remaining twelve it proved more serviceable. Eight of these were men, and four women. In two of the cases, lepra vulgaris of from fifteen months to two years' duration, arsenical and iodic preparations had been previously tried; in the younger patient the arsenic at first seemed to do good, but the improvement soon ceased. An ointment prepared with two scruples of concrete naphthaline to thirty of lard was applied, causing the scales to fall off, leaving the skin of a violet colour, with white circles around. A perfect cure was effected in six weeks, and although three months have passed since, there has not been any relapse. In four other cases the men were labouring under inveterate psoriasis; in one of them it had existed sixteen years, and had resisted arsenical, iodic, and mercurial treatment. The tar ointment was had recourse to, and with decided advantage, but the man becoming impatient on account of his business, an ointment of naphthaline, twice the strength of that used in the preceding cases, was spread on compresses, and applied over the diseased parts night and morning. The man was cured in six weeks. When the ointment was applied too strong, it caused a burning heat, which was soon removed by emollient baths and poultices. The other six cases were also instances of psoriasis cured by the naphthaline ointment. Dr. EMERY states, that this remedy has an unpleasant odour, which passes off, and it is apt to irritate the skin and cause erysipelas, if it be not carefully watched.]

58. *C.* The state of the constitution, as well as of general and local action, should guide the physician in the choice of remedies, which ought to be chiefly antiphlogistic and evacuant, in the acute or early stage, and alterative and depurative in the chronic or advanced states. In many cases, however, alteratives and depurative remedies require to be combined with tonics and even with chalybeates; especially in *cachectic habits*, and when the eruption assumes a livid or dusky hue. In these, the iodide of potassium with the carbonate or solution of potass and sarsaparilla, or tonic infusions, or the iodide of iron with sirup of sarsaparilla, or the bi-chloride of mercury in the tincture or decoction of bark, with tincture of serpentaria, or the fluid extract of sarsaparilla, will generally be of great service; and, if a cure be not effected by these, aided by external means (§ 61, *et seq.*), then the preparations of arsenic, or the combinations of arsenic, iodine, and mercury, may be resorted to, as above recommended.

59. *D.* The syphilitic varieties of squamous eruption should be treated with strict reference to the history of the case, and the means which have already been employed and the period of their employment. Several severe cases of this eruption, some of which had either gone

on to extensive ulcerations or become complicated with disease of the throat, or the bones or joints, have at sundry times come under my care. For these there are certain remedies, which, if judiciously employed, may be viewed as specifics.—*a.* The oldest and not the least efficacious of these is the *bi-chloride of mercury*, prescribed either in the manner recommended by VAN SWEITEN, or given dissolved in alcohol, and taken in water with the hydrochlorate of ammonia, or in decoctions of sarsa, &c., or prescribed with the decoctions or infusions, or tinctures of cinchona, serpentaria, &c. When the eruption and its antecedent symptoms have not been attacked by a mercurial course, then the bi-chloride should be given in decided doses, and preferably soon after a full meal, either in the form of a pill and in gradually increased doses, as advised by VAN SWEITEN, or as just recommended, in either of which combinations it may be taken in the intervals between meals. Salivation, unless it be slight, need not be produced; although the specific effects should be continued for some time; when either of the other remedies next to be noticed should be prescribed, if the eruptions have not nearly or altogether disappeared.

60. *b.* The next specific remedy for this species of eruption is *iodine*. I believe that this substance, or any of its preparations, had not been prescribed for any form of syphilitic disease when first I ordered it in the summer of 1825, the formulæ, as well as an ioduret of sulphur, having been prepared by Mr. MORSON, the eminent operative chemist. At first I employed the iodine either in the form of a weak tincture, or in combination with potash, or the iodide of potash with the addition of pure iodine. Subsequently I preferred the iodide of potash, conjoined with liquor potassæ and sarsaparilla; full doses of PLUMMER'S pill being taken at bedtime. The iodides of mercury have more recently been employed for this eruption, and are generally beneficial; but they are not superior to the treatment which preceded them. They are, however, advantageously given in the form of pills at night, or night and morning, the iodide of potash being taken during the day, with liquor potassæ and sarsa. In the syphilitic species, also, Mr. DONOVAN'S solution is an excellent remedy, and may be advantageously adopted in the more protracted cases.

61. *E.* The internal and external use of mineral waters, either natural or artificial, and of simple or medicated baths, will generally promote a cure. It is preferable, however, not to have recourse to these until morbidly increased action and vascular or excrementitious plethora is removed by depletions, emetics, purgatives, antimonials, &c. But this end being attained, the sulphur waters of HARROWGATE, LEAMINGTON, MOFFAT, CROFTON, and of other springs in this country; or of those of BAREGES, CAUTERETS, BAGNERES, BAGNOLES, &c., on the Continent, will be employed with great advantage. A frequent use of warm baths, the patient remaining in them for a considerable time, and using gentle friction over the affected parts, will often be of service. A small quantity of the sulphuret of potash may be added to the bath. If the eruption be attended by much itching, the biborate of soda dissolved in the water will prove very beneficial. Dr. DUFFIN recom-

mends the immersion of the part, especially when the extremities are chiefly affected, in warm artificial Harrowgate water; or the diseased parts to be washed or fomented with it twice or thrice daily, for fifteen or twenty minutes each time; and a mixture of equal parts of the weak citrine and tar ointments to be applied after each fomentation. The following formula is given by him for the preparation of this water: Sulph. magnesiae,  $\text{zj.}$ ; supertart. potassæ,  $\text{gr. x.}$ ; sulphat. potassæ cum sulphure (or sal polychrest),  $\text{zss.}$  These are directed to be dissolved in twenty-four ounces of warm water, and used for a wash or fomentation. I have lately employed a wash or fomentation, either warm or tepid, with tar-water, containing biborate of soda dissolved in it.

62. If the scales adhere or are accumulated in crusts, sulphureous vapour baths, followed by frictions, or gently stimulating ablutions, or fomentations, with a solution of the biborate of soda, or with a little liquor potassæ, will be of service. The application of steam or vapour, with or without the fumes of sulphur, is always of use. Lotions of diluted alcohol, of solutions of sulphuret of potash, or the decoction of dulcamara, will aid the exfoliation. When the scales are removed, BATEMAN and THOMSON recommend the unguentum picis, or the unguentum hydrargyri nitratis, diluted with the ceratum plumbi compositum, or with simple ointment; or, which is better than either, an ointment composed of equal parts of these two ointments. The ointments which I have preferred are the *ioduret of sulphur ointment* ( $\text{gr. xij.}$  or  $\text{xj.}$  to  $\text{zj.}$ ), the *calomel ointment* ( $\text{zj.}$  to  $\text{zj.}$ ), the *ointment of white precipitate*, the *zinc and lead ointments conjoined*, and the several *ointments of the nitrates of mercury* and of the *iodide of mercury*. These last should, however, be employed more or less diluted. The ointments containing either of the iodides are most suited to very obstinate cases, the others for slight or recent cases. The iodide of sulphur ointment was first employed by the author in 1825. The ointments should be applied at night and washed off in the morning with a saponaceous or alkaline lotion (as  $\text{zij.}$  of liquor potassæ in  $\text{zviij. ss.}$  of water), after which a solution of the bi-chloride of mercury in dilute alcohol ( $\text{gr. ij.}$  in  $\text{zj. p.}$ ) may be applied slightly by a sponge over the part. Besides these ointments, others, with the acetate or phosphate of mercury, with the sulphate and deutoxide of antimony, with an ioduret of ammonia ( $\text{zj.}$  to  $\text{zj.}$ ), with camphor, or with concrete naphthaline (two to four parts to thirty parts of lard), have severally been recommended by different writers. A principal advantage derived from ointments is the protection of the inflamed surface from the action of the air, to which very insufficient attention has been directed in the treatment of cutaneous inflammations. Therefore, after the surface has been cleaned by any of these ointments, they should be washed off, and some gelatinous, albuminous, or gummy preparation applied to it, so as to exclude the air, as advised for PITIRIASIS (§ 27); and this preparation should be allowed to remain as long as it answers this purpose, when it should be removed by fomentations and ablution, and reapplied until the parts are completely restored. I have lately employed for scaly eruptions a lotion of

one part of *Glycerine*, to three, four, or five parts of water, with marked benefit; and Dr. GLOVER has recommended *Iodoform* externally (3ss.—3i. to the ʒj. of cerate), and internally, in doses of two or three grains twice or thrice daily.\*

63. As I have shown in the article *PSYRIASIS*, the chief causes of the obstinacy of scaly and other cutaneous eruptions, are, 1st. The action of the air, from which they are not sufficiently protected during the treatment; 2d. The want of due attention to the state of the assimilative and depurative functions of the blood; and, 3d. Insufficient restrictions on diet and regimen. But, even when a cure is obtained, or nearly obtained, a *relapse* or a *return of the eruption* is a frequent occurrence—a relapse generally proceeding either from the causes just specified, or from a premature relinquishment of treatment; a subsequent return of the disease resulting from the same causes as produced it at first, or from inattention to the several digestive and excreting functions. Both these unfavourable contingencies are most likely to occur when the functions of the several abdominal organs have not received due attention during the treatment, and a restoration of them to the healthy state has not been effected; and also when the healthy conditions and colour of the parts affected have not been completely restored before the successful means were relinquished. These two causes, especially when acting simultaneously, with errors in diet and regimen, are most influential in producing relapses, and returns, at more or less remote periods, of scaly eruptions; and they are of greater importance than they have hitherto been considered.

64. The local forms of *psoriasis* and *lepra*, mentioned above (§ 16, *et seq.*), require chiefly the adaptation of the general and local treatment already described to the circumstances of each case.—(a) *Psoriasis palpebrarum* will often be benefited by the application of three or five leeches behind the ears, and by a lotion consisting of a weak solution of the nitrate of silver, or a lotion of sulphate of zinc, or diluted tincture of iodine, to the part. The calomel ointment, or the zinc ointment, or a diluted nitrate of mercury ointment, may be severally applied in this and the other local forms of the eruption.—(b) For *psoriasis genitalium*, emollient local baths, and the use of the lotions and ointments just mentioned, are most beneficial. If these forms be attended, as they usually are, with much itching or irritation, a solution of the bi-borate of soda in tar water, or in some emollient fluid, containing creasote, applied as a lotion, or by a sponge, will generally give relief and remove the eruption. Sulphur and cinabar fumigations are usually successful when the scrotum or anus is implicated.—(c) For *psoriasis palmaria*, after soothing the parts with local baths of the decoction of bran, &c., ointments containing the iodide of sulphur, or the iodide of mercury, or the other ointments already mentioned, may be employed in aid of the constitutional remedies recommended. In the more chronic states of *psoriasis palmaris*, Mr. WILSON advises a spirituous lotion of bichloride of mercury, followed by water dressing.

65. The mineral acids have been favourably

mentioned by some writers; but I have seldom observed much benefit derived from them, and have even believed them to have been sometimes injurious. In a few cases, however, after a due evacuation of accumulated secretions and excretions, the liver still continuing torpid, the nitro-muriatic acids given internally and employed externally have appeared of some use; and the sulphuric acid has occasionally been added, with marked advantage, to the neutral sulphates, dissolved in bitter infusions, and taken in quantities sufficient to keep the bowels freely open. Dr. C. SMITH and Dr. CUMMINS, however, are of opinion that dilute sulphuric acid possesses considerable efficacy in the treatment of squamous eruptions; the latter physician believing that the acid is decomposed, and that the system is thereby impregnated with sulphur. This may be the case when the quantity taken is small or very moderate; but in some experiments I found that the dilute acid, when given in large and frequent doses, could be detected unchanged in the urine. Acids, however, ought to be employed with caution, and with strict reference to the excretions, especially the urine and its saline constituents.

66. The diet and regimen are of the greatest importance in the treatment of all the scaly eruptions, and are often more beneficial, if strictly enforced, than even medical means. Animal food should be used sparingly; and pork, veal, ham, dried or smoked and preserved meats; fish and shell-fish, especially fried and rich fish; rich sauces, doughy articles, pastry, or pie-crust; pickles and preserves; heating and stimulating beverages, especially spirituous and malt liquors, coffee, punch, acid wines, &c., ought to be constantly avoided; and sugar, butter, and sweet or acidulated articles very sparingly taken. The remarks offered on this topic in the article *PSYRIASIS* (§ 34), a species of the eruption now treated of, strictly apply to the treatment of these eruptions.

## PUERPERAL STATES AND DISEASES.

—THE PATHOLOGY OF PARTURITION.—DISEASES INCIDENTAL TO THE PUERPERAL STATES.

CLASSIF.—GENERAL PATHOLOGY.—SPECIAL PATHOLOGY.

1. Several of the diseases incidental to parturition and to convalescence from this act are discussed under their special denominations; and to these I shall refer as they successively take their places in the group of maladies usually called "*Puerperal*." In this place, therefore, it chiefly remains to discuss, 1st. *The pathological relations of the puerperal state*; and, 2d. *The very dangerous and often malignant maladies incidental to it, which are not treated of under other heads*. That a view of the pathological relations of the puerperal state, impartially exhibited, and without reference to peculiar doctrines, will be of use, it is hoped, in guiding the inexperienced during their intercourse with the deviations from the more common procession of morbid phenomena which will occasionally be met with by them, is only a reasonable expectation; and hence an inducement to undertake the labour which a faithful exhibition of this view involves.

2. I. THE PATHOLOGY OF THE PUERPERAL STATES.—i. OF THE STATE OF THE FEMALE AT THE MOST ADVANCED OR FULL PERIOD OF PREGNANCY.—The changes, as well as the principal deviations from the healthy state, during utero-gestation, are described in the article PREGNANCY, and under various other heads. It only remains to notice the state presented by the female economy when gestation is approaching, or has reached its full period. The uterus then has attained its utmost size; and it then enjoys a copious determination of blood for the nourishment and growth of the fœtus, and for the preservation of its own augmented structure. The distended uterus, especially in a first pregnancy, presses more or less, according to the size of the female and the capacity of the abdomen, upon the other viscera, especially on the urinary bladder, the kidneys, the rectum, and large bowels, the liver and biliary apparatus, and stomach; and, consequently, the descent of the diaphragm is impeded, and congestion of the lungs is favoured. But the pressure also influences the circulation through the large venous trunks, and often, in some degree, through the heart and lungs; hence arise congestion of remote parts, especially of the veins of the lower extremities, often followed by

cedema, and congestion of the sinuses within the cranium, with the dangerous consequences of this condition. The effects produced by the large size of the uterus are very much aggravated if pressure upon the lower bowels be allowed to interrupt the regular process of fecation and excretion, and if this cause or indigestion should give rise to flatulent collections in any portion of the alimentary canal.

3. With the increased development of the pregnant uterus, the peritoneal envelope of the organ, and even the ligaments experience a remarkable change, and are inordinately stretched, so as to favour the supervention of inflammation, especially upon the removal of the distending cause, when additional influences come into operation. With the ascent of the fundus of the uterus, the omentum is more or less displaced, and carried upward; its exact position and influence upon adjoining parts varying with the quantity of adipose substance it may contain.

4. It is obvious that changes of the position and condition of the viscera must influence more or less the functions performed by these viscera; and that, both during the progress of these changes and at their consummation, various disorders, noticed under PREGNANCY, are liable to appear; that the secretion and excretion of urine should be disturbed or impeded, or even arrested, the functions of digestion and assimilation disordered, the intestinal secretions and excretions interrupted, and sensibility and motion materially disturbed. At the full period of gestation, the circulating and respiratory organs, and still more the nervous centres, owing to the congestions to which they are exposed at this period, are severally liable to the most serious attacks as soon as the congestion, in which these attacks originate, is carried to the pitch requisite for their development.

5. In connexion generally with the changes now mentioned, if not always dependent upon these changes, the nervous system generally acquires increased sensibility and susceptibility of impression; and, through the medium of this system more directly, and through that of the vascular system more indirectly, the whole frame intimately sympathizes with the uterus, independently of the mechanical effects produced by it upon the other viscera. The nervous development of this organ, and the vascular determination to it, influenced by the nervous organization, renders the womb the centre of numerous sympathies and the source of many morbid phenomena, all which increase and become more prominent with the progress of pregnancy, and still more manifest at the full period, during parturition, and for some time after delivery. The activity of the nervous influence, and of the vascular circulation of the uterus at an advanced stage of pregnancy, influences remarkably the conditions of both the nervous and the vascular system generally, notwithstanding the various pathological conditions tending to impair the energy and sensibility of the one, and the tone and action of the other—notwithstanding interrupted excretion, and the various circumstances favouring excrementitious contamination of the blood, and congestion of it in venous trunks and sinuses.

6. ii. OF THE CHANGES TAKING PLACE DURING THE PARTURIENT PROCESS, AND THEIR INFLU-

**ENCES IN CAUSING DISEASE.**—The uterus, having completed its function of fetal development, or having carried this function as far as is consistent with the health and subsequent safety of the mother, experiences that state of action which is the best calculated to preserve both the child and the parent from injury and disease. But during this action, and the changes in the nervous and vascular systems which it more or less remarkably produces, various morbid conditions are apt to appear. The painful contractions of the uterus, although occurring only at intervals, tend to excite or react upon the nervous systems generally, but more remarkably upon the spinal cord, and through it upon the brain. These contractions also tend to diminish the flux of blood to the uterus, and to determine it in greater quantity to the brain, and thereby to change a pre-existent state of passive congestion into active and increased congestion, or to carry a condition of the vascular system, which was insufficient to produce acute disease, to that pitch which instantly develops such disease.

7. The uterine actions, although often thus productive of seizures depending upon the states of the cerebro-spinal nervous centres, especially as regards the circulation of these centres and the peculiarities of that circulation, are yet independent of these states. This fact is undeniably demonstrated by the occurrence of uterine action independently of the will, and during abolition of the functions of the cerebro-spinal system; by natural parturition taking place during paraplegia as well as hemiplegia, and as shown recently by the regular progress of the parturient process, while sensibility and voluntary motion are abolished by the inhalation of ether or of chloroform. It is obvious that the muscular contractions, and the painful excitement of the uterine nerves during parturition, will occasionally develop morbid tendencies in the nervous system when these already exist, owing either to hereditary or to acquired predisposition, and consequently that convulsive or apoplectic seizures, or phrenitic or maniacal attacks will occasionally appear during this process; the convulsive seizure presenting more or less of the apoplectic, of the epileptic, or of the simply convulsive character, according to the predisposition and peculiar circumstances of the case; the maniacal attacks rarely appearing during parturition, although frequently after this process. Convulsive seizures are not confined to parturition, for they occasionally take place previously to, as well as after, this process; but during it they are more apt to assume an apoplectic or epileptic, or a mixed form—in consequence of the greater liability to active congestion of the brain and spinal cord during the parturient act—the apoplectic being characterized by profound coma and stertorous breathing, with slight convulsions, the epileptic by the violence of the convulsions, by frothing at the mouth and injury to the tongue. (*See articles CONVULSIONS, PUERPERAL; and INSANITY, PUERPERAL.*)

8. Certain changes in the uterus itself may take place during pregnancy, or even may have existed previously, and may arrive at a dangerous or even fatal termination upon the accession or in the course of parturition. Thus in-

flammation may have attacked a portion of the pregnant uterus and occasioned softening, or impaired action and tone, or even a greater lacerability of that portion, in consequence of either of which changes rupture of the uterus, or dangerous hemorrhage may take place during parturition; or, if either of these do not supervene, inflammation of the uterus, or of its veins or sinuses, or peritonitis, or puerperal fever, may follow delivery, the previously diseased state, and the exhausted tone and contractile power of the organ especially favouring the occurrence of these maladies.

9. There are various circumstances connected with parturition productive of disease either of the uterus or of adjoining and associated parts. The interferences arising out of impatience and want of confidence in the efforts of nature, a premature or inconsiderate, or a too long delayed recourse to medicinal or mechanical aids of parturition, and the injury which these may occasion either to the uterus or to parts in the vicinity, or even to both, are among the most influential causes of disease, not only of the parts thereby injured, but of the frame generally through the media of the nervous and vascular systems. The means which have recently been recommended for the prevention of pain during parturition, although quite competent to the production of this result, cannot be viewed as altogether innocuous. Several instances have already occurred, evincing not merely dangerous, but actually fatal effects from recourse to them. A fatal issue may certainly be prevented from taking place immediately from these means; but the changes which may terminate fatally cannot be so readily prevented in all cases, and at the same time accomplish the intention for which they are employed. These anæsthetic agents have been demonstratively shown not only to destroy sensibility for a time, when inhaled for a short period, but also, in comparatively short periods of inhalation, to produce congestion of the lungs, a manifest change in the state of the blood, and even a rapidly fatal result. That these agents, when adroitly and cautiously administered, may not occasion any inconvenience subsequently to their inhalation may be the case, in nine out of ten instances in which they have been employed, will be readily admitted, but the tenth instance may be one of serious puerperal disease, of convulsions, or of mania, or of fever, or of congestive pneumonia, or bronchitis, owing to the previous state and predisposition of the patient: events which cannot be anticipated or guarded against by the physician. Pain is often salutary as respects its effects, and especially in enabling the œconomy to resist, and to rally against, the depressing operation of shocks upon the vital influence; and, when neither its violence nor its continuance is productive of injury to the constitution, or of exhaustion of vital power, to endure it is preferable to the annihilating of sensibility by an agent which acts so remarkably, and so immediately upon the chief manifestation of animal life, arrests the usual processes of nature, and even terminates existence itself if employed a few seconds longer than is required to destroy this the highest function of living creatures.

[On the other hand, it is not to be forgotten

that very serious consequences often happen from the shock produced by pain itself, as in a severe surgical operation, or from parturient throes, and that there may be less danger in overcoming these pains, and thus preventing the shock, than in allowing them to go on unimpeded. There is a choice of evils, and, if possible, we are to select the least. We have been led to believe, from what we have observed, that the general employment of anæsthetic agents in midwifery is inexpedient, being not unattended with danger. Dr. J. O. WARREN has very justly observed, that there is no parity between the abolition of pain in surgical operations and the abolition of the pains of labour, the former being only a part of that general law for preservation against injury, in consequence of which, whenever a foreign body threatens to impair the integrity of an organ, pain is produced, and the organ is instinctively withdrawn from the contact. While, therefore, there is nothing contrary to the laws of nature in the removal of pain from surgical operations, that which regulates the pains of labour is a general law, its final cause being sufficiently plain to show its utility, if not its necessity. It would certainly seem, *à priori*, that the use of so powerful an application through the whole period of a natural labour would, in proportion to the term of that labour, increase the dangerous tendency to organic excitation; and when this period is very protracted it might bring on distressing derangements of the stomach, brain, spinal marrow, or uterus, besides in many cases suspending the uterine contractions. Dr. W. is of opinion that the cases in which ether or chloroform can be properly resorted to in midwifery should be exceptions; such as, 1st. In a natural labour, when the pains are uncommonly severe, especially the terminating pains in a first parturition. 2d. During limited periods of labours prolonged by a preternatural cause. 3d. When, from the peculiarity of constitution, the patient cannot without danger support the usual amount of suffering. 4th. For the purpose of obtaining relaxation in irregular contractions of the uterus, as the hour-glass contraction after delivery.

On the contrary, there are other highly respectable accoucheurs who advocate the general use of anæsthetic agents in midwifery practice, as Professors SIMPSON, of Edinburgh, and W. CHANNING, of Boston, Mass. The former states that he has employed chloroform in almost every case of parturition for the last six months or more, not only without danger, but without any unpleasant symptoms. The testimony of Dr. CHANNING is also to the same effect. The conclusion, then, to which we are forced to come, in consideration of all the facts before us, is, that in properly-regulated doses, anæsthetic agents, like other powerful narcotics, as morphia, &c., may be administered not only with safety, but with the highest advantage, provided there be no contra-indicating circumstances, and due attention be paid to condition, age, temperament, sex, and constitution. We have found a small inhaler the most convenient method of giving chloroform, so as to regulate the dose with proper exactness. In this vessel place fifteen to twenty drops of pure chloroform, and let the patient inhale it carefully; if the dose is not sufficient, add ten or

fifteen drops more, which will usually be found an ample quantity to annul sensibility, if not consciousness.]

10. iii. OF THE STATE OF THE FEMALE AFTER PARTURITION, AND ITS INFLUENCE IN FAVOURING THE OCCURRENCE OF DISEASE.—In estimating the state of the female upon delivery, the previous conditions now passed in review, those just antecedent to parturition, and the act of parturition itself, ought to be held in recollection. The pressure produced by the gravid uterus upon adjoining viscera, and the effects of that pressure, as shown above (§ 6, *et seq.*), are now suddenly removed. The vitality of the frame has sustained some degree of shock from the violent contractions of the uterus, the expulsion of the fetus, and the detachment of the placenta, as well as from the sudden loss of blood, and the removal of pressure and distention. The internal surface of the uterus, moreover, resembles that of an extensive wound, especially where the placenta was attached to it; while the peritoneal surface of the organ, and the positions and physical conditions of the several abdominal viscera, are now more or less changed. The general results of these concurrent changes are not severely felt by robust or sound constitutions, beyond what may be viewed as a slight shock to the vital energy, attended by more or less exhaustion consequent upon the pains, the uterine action, and the loss of blood; but this result in these constitutions amounts not to disease; it is merely a state of vital exhaustion, which nature soon repairs, but which readily favours the development of disease whenever any of the causes to which puerperal females are often exposed comes into operation. It is different, however, with females who are otherwise circumstanced, especially with the delicate, the insufficiently nourished, and the morally depressed. If there exist a deficiency or poorness of blood; if fecal accumulations have formed in the large bowels; if the patient be nervous, hysterical, or subject to sudden or epileptic seizures; if she entertain fears of her state, or anxieties as to the present or future; and if she be exposed to the impure air of a low, miasmatic, damp, and close chamber or locality; or to the contaminating and infectious air of an hospital; or to any of the numerous causes which induce the diseases incidental to child-bed, then the effects, whatever may be the especial form which they assume, will be most serious and often fatal.

11. In proportion to the severity of shock produced by the parturient act upon the vital energy, and to the susceptibility of the nervous influence and sensibility of the patient, will the liability to the supervention of puerperal maladies be great. Mania, watchfulness, headache, convulsions, imperfect contractions of the uterus, or an impeded return of the organ to the size proper to the time which has elapsed since delivery; suppression of, or irregularities in, the lochial discharge; suppression of the secretion of milk, &c., may severally follow severity of shock, especially when heightened by marked susceptibility and sensibility; and these latter will in their turn be greatly aggravated by large losses of blood relatively to the condition of the vascular system, even although no other malady be superinduced. After consid-

erable hemorrhage, also, particularly when vital exhaustion is remarkable, or when the mind is anxious or depressed, morbid emanations strongly impress the nervous system, and readily pass, by endosmosis, into the pulmonary circulation. The contractions of the uterus being then also inefficiently produced, the lochial discharge is partially retained and rapidly altered; and, thus altered, it is partially imbibed by the vessels opening on the internal surface of the uterus, inflaming these vessels and venous sinuses. But the matters retained in the uterus may not merely inflame these vessels, they may also contaminate the organ itself; and being imbibed and absorbed into the circulation, contaminate also the whole mass of blood, with or without manifest change in the uterine vessels and structure; and, moreover, after such contamination, superinduce remarkable constitutional effects and structural lesions of those parts especially which have undergone the more evident alterations as to position and condition during the successive stages of gestation and parturition.

12. Thus, after parturition, the female frame is particularly open and liable to be invaded by the most influential causes of disease: 1st. By mental excitement and impulse, and by moral depression. 2d. By the inhalation of morbid effluvia, proceeding either from other diseases, or from the decomposition of animal discharges and secretions, or from the other sources generally productive of infectious emanations. 3d. By the absorption from the cavity of the uterus itself of retained and partially decomposed discharges. 4th. By infectious matters retained in the foul bed-clothes, mattresses, or beds in which the female is confined. 5th. By the retention and absorption of altered secretions and excretions, or of fecal matters from the alimentary canal; and, 6th. By interrupted secretion and excretion, the blood being altered more or less, owing to the accumulation in it of morbid or excrementitious materials.

13. IV. OF CONVALESCENCE AFTER PARTURITION.—A. THE NATURAL COURSE OF CONVALESCENCE.—a. The shock consequent upon delivery soon subsides when it is moderate and the patient obtains a few hours' sleep, if all disturbance or excitement be prevented. In proportion to the subsidence of this effect upon the vital power, the comfort and repose of the patient return, and nervous symptoms or vascular excitement are prevented. As the shock subsides and exhaustion is diminished, so are the several secretions and excretions, with the new secretion of milk, re-established. The circulation, as indicated by the pulse, which was excited or increased in frequency during the progress of labour, falls below the natural standard immediately after, and continues below it during a few hours. After varying somewhat for the following fourteen or fifteen hours, the circulation becomes slightly increased on the secretion of milk; and, when this secretion is established, it generally continues about the natural state.

14. b. The uterus contracts more or less firmly immediately after delivery, so as to reduce it, in the more energetic cases of contraction, to about the size of the infant's head. This contraction, 1st. Prevents hemorrhage; 2d. Empties the cavity of the uterus, and prevents

the lodgment of coagula; 3d. It constricts the uterine vessels and sinuses, evacuates their contents, and prevents their tendency to imbibed fluids, which may be retained in the cavity of the womb; and, 4th. It diminishes the afflux of blood to the uterus. The contraction and diminishing size of the womb proceed, although not regularly, or without recurrences of slight relaxation, until about the eighth, or ninth, or tenth day, when it descends into the pelvis. Previous to the eighth day, its state may be ascertained through the relaxed abdominal parietes; but afterward the fundus only can be felt above the pubis, and in six or seven days it can no longer be detected. This diminution of bulk is not altogether attributable to contraction, but to absorption in part, and in no small degree to the exclusion of the supply of blood, and to the pressure, by the contraction of the uterine fibres, of the fluids from the vessels and the interstices of the structure. It may, however, be doubted whether absorption is concerned in lessening the size of the womb after delivery, the lochial discharge probably contributing to this result.

15. c. The condition of the internal surface of the uterus, after delivery, is a matter of interest. "For several days after parturition, when no disease of the uterus has supervened, its lining membrane is coated with a yellowish brown, dark red, or ash-gray coloured layer of no great thickness, which seems to be formed chiefly of the fibrine of the blood, with small portions of deciduous membrane." The part to which the placenta was attached is raised above the surrounding level: its surface is unequal, resembling in this respect a granulating ulcer; its size is wonderfully reduced. In this situation dark-coloured coagula are found sealing up the orifices of the uterine sinuses, and frequently extending into the veins. The structure of the uterus is found to be less dense than natural, and the fibres more distinct. The os and cervix uteri are covered with ecchymoses, as if severely bruised; and sometimes small lacerations are observed on the edge. The orifice remains open for some days, but gradually closes. The vagina soon recovers its former calibre; considerable heat and soreness of it are experienced for only a short time, unless the head of the child have remained long in the pelvis, or the lochia be very acrid, when they are prolonged or pass on to inflammation of a more or less severe character. The vulva also resumes its natural capacity in a shorter time than might be expected. (See CHURCHILL.)

16. d. After-pains require no mention at this place, as they are considered under that head. (See art. AFTER-PAINS.) The lochia is merely a continuation of the discharge of blood which attends delivery, and proceeds from the vessels exposed by the separation of the placenta. For three, or four, or five days it continues of a red colour; but it is much thinner, and more watery than blood, and it is not coagulable. It then sometimes becomes yellowish, retaining its serous consistence; but it most frequently changes successively to greenish, yellowish, and, lastly, to a turbid appearance. The quantity and continuance of this discharge vary remarkably. Of the former no estimate can well be formed; the latter varies much; but the discharge seldom ceases altogether in a short-

er period than three weeks, unless in consequence of disease, or continues longer than a month. Its sudden disappearance, and even its short duration or scanty quantity, are important symptoms of puerperal disease.

17. *c.* The several secretions and excretions are more or less affected during the puerperal states. During parturition the *perspiration* is abundant, but diminishes gradually after delivery; but it usually continues free, and has a faint, sickly odour, until convalescence is fully established, when the skin presents its usual state. The *urine* varies in quantity with the abundance of perspiration and of fluid ingesta, and also with the *state of the bowels*, which also vary, owing to their previous conditions and other circumstances. The *milk* is secreted immediately, or soon after delivery. A serous fluid, approaching to, but in some respects differing from true milk, is generally secreted for some time before parturition; and occasionally true milk is secreted during labour, although rarely with first children. In this case the mother can suckle immediately after delivery. But more frequently the milk is not secreted for eighteen, or twenty-four, or thirty-six hours, when the breasts enlarge and stinging pains shoot through them. As the parturient shock passes off, and the contracted state of the uterus diverts the vascular determination from this organ, the secretion of milk commences and increases.

18. *f.* With the development of this new function a general disturbance of the system, constituting what is termed the *milk fever*, is produced. The severity and duration of this disturbance are influenced chiefly by the circumstance of the woman's nursing the infant or discouraging the secretion of milk, and by the state of the bowels and of the other secretions. At first, or about the second or beginning of the third day, the mammae are heavier, larger, and tenser, and the patient has slight chills or rigours, followed by heat of skin, soreness of the breasts, and acceleration of pulse. With these symptoms the secretion commences, at first slowly and with difficulty, but afterward more freely. As the secretion becomes more abundant, the above symptoms abate, and in two or three days disappear. The milk first secreted is thicker and richer than that which follows, and acts as an aperient to the infant. (*See art. LACTATION.*)

19. *B.* DEVIATIONS FROM THE NATURAL AND HEALTHY COURSE OF CONVALESCENCE AFTER DELIVERY. — Dr. HAMILTON justly remarks, 1st. That when there has been unusual suffering during labour, the usual changes after delivery cannot be expected to proceed in a healthy manner, because the exhaustion of sensorial power must more or less paralyze the actions of every part of the system; 2d. That the violent pressure to which the parts concerned in the mechanism of labour have been subjected must occasion a tendency to inflammation; and, 3d. That the violent and continued actions of the respiratory organs must render them liable to derangement. But, however influential these causes may prove in occasioning deviations from the ordinary course of convalescence, there are others not the less so, and these consist, 1st. Of disorders previously existing, or occurring during pregnancy; 2d. Of

peculiarity of constitution or predisposition; 3d. Of mental agitation and moral influences; and, 4th. Of numerous circumstances occurring, and of causes coming into operation after delivery.

20. (*a*) The *nervous shock* may be so very severe as to create alarm. The patient has the aspect of a person in a state of collapse or extreme exhaustion. The countenance is expressive of anxiety; the senses are either morbidly acute, or, what is still worse, unnaturally dull; the pulse is very rapid, small, and weak, or very slow, laboured, or irregular; and the respiration is hurried, panting, and often more frequent than accords with the state of the pulse. Between this more extreme state of vital shock and the natural state there are numerous grades; and even in the slighter states reaction may be long deferred, or may take place imperfectly, or even excessively. In the more extreme states of shock, death may occur in a few hours, without any attempts at reaction being made, the vital sinking proceeding until life is terminated.\*

21. *Dissection*, in these cases, detects no lesion to account for death. Dr. CHURCHILL remarks, that of several cases of this kind which he has seen, one was tedious, but terminated naturally, and two others were instrumental deliveries. A due estimate of the nervous shock is of great importance in severe cases; for in most instances the progress of convalescence is in inverse proportion to the amount of this disturbance. In some persons slight circumstances increase, in a wonderful degree, the susceptibility of impression; and, if this be overlooked, very serious results may follow.

22. (*b*) The *state of the pulse* is of the utmost importance after delivery. If it continue frequent or very quick, one of two, or even three, things is to be apprehended, even although no other untoward symptom may exist, namely, hemorrhage, internal or external, or the accession of inflammation, or of puerperal fever. Dr. CHURCHILL observes that, in almost all the cases of flooding after labour, he has found the pulse remain quick, and perhaps full, up to the occurrence of the attack. He might have extended the observation to inflammations and puerperal fevers; seeing that the phenomenon is equally applicable to them and to the commencement of lactation, to after-pains and to the retention of coagula, in some constitutions. The remark of Dr. JOHN CLARKE that no woman should be considered as safe whose pulse exceeds 100 is certainly just; and I may add, that if the pulse exceed 110, then the risk of puerperal fever or of internal hemorrhage having commenced, is very great; and a careful examination of all the symptoms of the case should be made, and the coming mischief anticipated, and, if possible, prevented.

23. When, with increased quickness of pulse, it is found that the uterus has not decreased so far in size as might have been expected from the time that had elapsed since delivery, or

\* We have known several cases of death from nervous shock after child-birth even as late as the second or third week, in very delicate females, and where no morbid changes could be found after death. In two instances the fatal result was caused by strong mental excitement when in a very feeble condition; syncope succeeded, from which the patient could not be roused. These cases require very great caution, in order to guard against accident.]

that, having been diminished, its bulk has increased about the fourth or fifth day, then inflammation of the womb or of its vessels may be expected to declare itself, if it have not already done so, by increased tenderness, by less firmness of the uterine tumour, by the diminution of the lochia, and by the sensations of the patient. These symptoms may, however, be occasioned by the retention of coagula in the womb; which, if retained long, or if not thrown off, by means which will aid the contractile action of the uterus, may cause inflammation or puerperal fever. As tenderness may accompany severe after-pains, it is proper to distinguish between the tenderness thus produced and that which depends on inflammation; and this may be effected by ascertaining whether or no the tenderness continues in the intervals between the pains and contractions which occasion them. If it does continue, inflammation should be suspected, especially if the pulse be quick, and if the lochia has suddenly become scanty or suppressed.

24. (c) The *lochia* rarely deviates from the usual condition without exciting some degree of anxiety in the mind of the patient and physician. This discharge may cease a few hours after delivery, after the birth of a still-born or putrid child; and, although putridity of the fetus may be viewed as risking the healthy condition of the uterus, yet the membranes may have protected this organ, so that no unpleasant symptoms appear. The lochia may also be very scanty, yet of the usual duration, as when flooding has occurred; and in this case no farther mischief may appear, although a greater predisposition to some other puerperal malady is thereby developed, as puerperal fever or mania, &c. This discharge may be, on the other hand, *excessive*, either as to the quantity within the usual time, or as to the prolonged duration of it. After having decreased in quantity and changed in colour, it may suddenly increase, or become even excessive. This is usually caused by sitting up too soon, or walking about; or by the expulsion of a clot which may have obstructed the passage of the discharge through the os uteri. If the lochia change suddenly from a paler to a redder colour, or if a *red colour* return after it has disappeared, the accession of secondary hemorrhage should be dreaded and guarded against. The passage of the discharge into uterine *leucorrhoea*, which may be permanent, will sometimes occur, and ought to be prevented. The lochia may assume an *acid* and a very *offensive* state. It is then of a dark or green colour, very profuse and watery, often so acid as to excoriate the parts, and always very fetid. These conditions of the discharge are often a sign of disease, but they often also are caused by the retention of a small portion of the placenta, or of coagula, either in the uterine cavity, or in the extremities of the veins and sinuses, or by portions of the decidua which putrify and come away.

25. (d) The *bladder* and *urethra* may suffer considerably after labour, especially when protracted, and be excessively tender; and redness and tenderness may extend to the *vagina* and *vulva*. This state is often productive of distressing strangury, sometimes with considerable fever.

26. C. OF THE MANAGEMENT OF CONVALESCENCE FROM PARTURITION.—(a) *For the natural course of recovery*, the recommendations of HAMILTON, CLARKE, SMELLIE, BURNS, CHURCHILL, and others accord in every respect, and are nearly the same as those which will be here adopted. The patient, after delivery, should be kept for some time in a state of perfect quiet. The room ought to be slightly darkened, and very few persons, except the nurse, admitted. Little or no talking ought to be permitted, unless in an under-tone, and no whispering. The conversation and demeanour of all should be cheerful; and no ill news, frightful stories, or unseasonable communications related. Mental excitement or emotion of every kind is liable to be injurious. The horizontal position must be strictly preserved, and sleep invited. After a few hours' sleep the nervous system will recover from its shock. The state of the *pulse* ought to be carefully watched, and excitement of it viewed attentively in connexion with every sign or symptom of disorder, as it is generally the first to indicate the approach of disease. "Immediately after delivery, it is proper to apply *compression* to the abdomen, by means of a broad binder. This is useful, in the first place, to fix the uterus, and secure its steady contraction; and, secondly, to encourage the contraction of the abdominal parietes. The binder should extend from the ensiform cartilage to the pubes, and be carefully applied for ten days or a fortnight." Immediately after the expulsion of the placenta, a warm napkin ought to be applied to the vulva, and changed at short intervals. "This will afford relief from the smarting pain consequent upon the passage of the child. After some hours, when the patient is recovered, the external parts should be washed with tepid milk and water, containing a small portion of spirit. This must be repeated twice a day, not only for the sake of cleanliness, but to aid in restoring the parts to their natural state."—(CHURCHILL, &c., *Op. cit.*, p. 253.)

27. The *horizontal posture* ought to be undeviatingly observed; and however the exact position may be changed, the horizontal state should never be departed from until permitted, and never until after the fourth or fifth day from delivery. The *after-pains* require such attention as is advised in the article respecting them. The *lochia* needs no farther attention than that the napkins should be changed sufficiently often, and that they be applied warm, and so as to prevent the admission of air, especially cold air, to the tender parts, and the action of the air on the internal surface of the vulva. The air in the chamber ought to be preserved in a fresh and moderately cool state, and a fire kept up in order to promote a renewal of air in the room. The bed-clothes ought only to be sufficient to afford a comfortable degree of warmth.

28. *Micturition* should be attempted as soon after delivery as may be felt to be requisite—in from five to eight hours—and it should take place as nearly in the horizontal position as possible. Dr. HAMILTON advises the patient to turn round upon her knees, by which any coagula accumulated in the vagina will readily be expelled. If micturition be neglected too long, the bladder may be paralyzed, or inflammation may attack it and extend to the peritoneum, or convulsions may be excited by its over-distension.

tion, as I have witnessed in two instances. If any difficulty in evacuating the bladder exist, a warm fomentation to the vulva, or the introduction of the catheter, will remove it. It is the more important that the urine should be voided when the patient complains of pain in the lower belly, with a desire to pass it, and when the labour has been severe or instrumental.

29. The bowels may remain quiet for twelve or eighteen hours after delivery; and if they are not moved at the end of this time, a dose of castor oil, or of senna, or of rhubarb may be given, and, if necessary, repeated. The frequency of repetition must depend upon the state of the bowels previously to delivery, and upon the presence of signs of fecal accumulations. Dr. HAMILTON remarks, that "unless it be unequivocally ascertained that the bowels have been regularly cleared previous to delivery, a dose of castor oil, or of aloes, with some narcotic, if necessary, ought to be given as soon as the woman has recovered from the shock of labour, and the appearance of the stools particularly examined." If indurated feces be present, the purgative should be repeated every ten or twelve hours, until the bowels are completely unloaded. When the reduction of the bulk of the uterus is tardy, purgatives are more especially required, or an enema, containing the spirit of turpentine and castor oil, may be occasionally administered.

30. If the breasts become hard and painful, warm fomentations, frictions with warm oil, or with a slightly stimulating liniment, and a dose of a purgative medicine are usually advised and repeated for those cases where the milk is to be discouraged, the woman not intending, or not being capable of suckling the infant. As soon as the secretion commences, the child should be put to the breast, in order to facilitate the discharge of the milk and to prevent distention. It is better, as Dr. CHURCHILL advises, to do this, even if the patient should not suckle her infant, as it will afford relief. When she is not to suckle, she ought to have every second or third day, according to her strength, till the secretion of milk ceases, and the tension of the mammae subsides, a dose of some purgative, as rhubarb or senna, with a neutral salt. She ought not to leave her bed, even to have it made, before the fifth day; and, if she be a delicate subject, she should strictly preserve the horizontal position for several days longer. Premature exertion, and inattention to position and to suitable diet, are the chief causes which combine with impure air, foul beds and bedding, and mental emotions to produce the maladies consequent upon parturition.

31. The patient's diet should consist chiefly of gruel, arrow-root, sago, rice, milk, whey, panada, weak black tea, with dry toast or biscuit, and very little butter for the first three or four days. When the vascular excitement attending the commencement of lactation has subsided, and no disorder is observed, broth, chicken, mutton, or other light articles of diet may be taken on the seventh or eighth day; and wine and water, preferably claret, may be allowed in a day or two afterward.

32. (b) *Deviations from the ordinary progress of convalescence* ought to be promptly attended to and cautiously treated.—a. If the vital shock be extreme, or even severe, small doses of opium,

with camphor, ammonia, or musk, should be frequently administered, and the quantity of each duly proportioned to the frequency of exhibition and the urgency of the case. These substances are preferable to wine or brandy, as they procure sleep, quiet the pulse, and prevent the subsequent reaction from being excessive; while the latter may occasion fever, or distressing headache, or even mania. In this emergency perfect moral and physical quietude should be preserved. As the shock subsides, suitable nourishment and restoratives are requisite.

33. *β. Increased frequency of pulse* ought always to excite suspicions and the strictest investigation. If the patient suffer from gastrointestinal irritation, the cause of frequency is thereby manifested, and blue pill, or the gray powder, with DOVER's powder, should be prescribed, and repeated according to circumstances. If fecal matters have accumulated in the bowels, the purgatives and enemata already mentioned are required. If the quickness of pulse still continue, the states of uterine contraction and of the lochia ought to be examined, with the view of detecting the commencement of disease in the uterus or its appendages, or in the peritoneum.

34. *γ. An acrid or morbid state of the lochia* is apt to occasion irritation, excoriation, or even inflammation of the vagina and vulva, with smarting and itching. In this case extreme cleanliness, frequent bathing, warm diluent vaginal injections, lotions containing lead, or the black-wash, or the sulphate of zinc may be employed; the simply diluent injections being first used, and the others subsequently or after the lochia has become scanty, or about to disappear, lest suppression of the discharge should be produced. The injections ought to be warm, and, if the lochia be very offensive, a small quantity of creasote, or of chloride of lime, or chlorinated soda may be added. During the treatment, the binder above recommended should be duly and carefully applied. When the lochia becomes excessive or prolonged, nutritious diet, tonics, as the preparations of cinchona, or quinine or chalybeates, or the tincture of the muriate of iron, ought to be allowed after a due time from delivery has elapsed. When the discharge becomes excessive, or changes in colour after having nearly ceased, the patient should be confined to the horizontal posture. In all these circumstances, and especially when the lochia is excessive, prolonged, or likely to pass into uterine leucorrhœa, the occasional administration of an enema containing oil of turpentine, or embrocations with this substance, applied either above the pubis or over the sacrum, will be of service.

35. *V. OF THE INFLUENCES AND AGENTS FAVOURING, PREDISPOSING TO, OR EXCITING PUERPERAL DISEASE.*—The same causes may produce any of the acute maladies incidental to the puerperal state; the particular malady being determined by the peculiar combination of causes and of circumstances aiding the development of the effects of these causes by the constitution, habit of body, and state of the patient previous to and during the parturient process, and by the changes consequent upon delivery; by these last more especially than by others. The remarks which have been offered above on the several changes

and varying states and circumstances tending strongly to predispose the female frame to the invasion of the exciting causes of acute disease, will sufficiently show the marked liability to such disease which these changes and states create, even in the more favourable circumstances in which she may be placed. But when it is considered that, with these successive changes, various mental emotions have been and continue in operation—fear and anxiety in most cases, and the most depressing of the moral sentiments in some—these changes must be viewed as receiving therefrom the most important aids towards the development of serious morbid effects. To these, moreover, are often added the influences of diet and regimen, not always the most suitable to the successive states of advanced gestation and of parturition, and more especially to the period immediately following delivery; the still more active agency of close, impure, and miasmatic air, of foul exhalations, and of imperfect ventilation; and the contingent operations of infectious effluvia variously generated and as variously conveyed and propagated.

36. Among the poorer classes, and even among the richer in some localities, the moist, putrid, and contaminating emanations from the numerous sources with which all cities and large towns more or less abound, are productive of the more malignant of the maladies incidental to the puerperal state. These sources have been fully described, and their influence shown in the articles *INFECTION* and *PESTILENCE*, *protection from*. But the most malignant operation of a foul or contaminated air is shown in lying-in hospitals, where every patient which enters them, at certain seasons or times, is seized with puerperal fever, or some other acute and often fatal disease. If the wards of a lying-in hospital contain more than four beds; if these wards are placed too close to each other; if they be not lofty and ventilated by a thorough current, by open fire-places, and by fires; if they be too closely shut during cold and moist states of the air; if the discharges be not quickly removed, and the cloths imbibing the lochia be not frequently renewed; and if the bed-clothes and bedding be not perfectly clean and duly purified, the more malignant forms of puerperal disease will soon make their appearance, owing to the generation of a morbid, an infectious, and a contaminated effluvia, by puerperal females and by their discharges, in too confined and insufficiently ventilated apartments. This effluvia, when once generated, may be conveyed by the clothes, or by other media, and may infect others so circumstanced as to be contaminated by it. Of this fact I have known numerous proofs, which will be noticed in the sequel.

37. There is every reason, moreover, to believe that lying-in hospitals are not the only source of the fevers which render these institutions a greater curse than a benefit to the community; for I have seen reasons for inferring, that the foul air extricated from the numerous sources of impurity, contamination, and death with which this city and others abound, and which I have described under the heads referred to above, especially when undiluted by due ventilation, or when accumulated in a humid, still, and confined atmosphere, and when admitted to and acting upon the recently delivered

female, will so depress organic nervous power, and so contaminate the circulating fluids, as to develop puerperal fever of a malignant character, which may, in its turn, generate an effluvia productive of a similar malady in other puerperal females when communicated to them.

33. The contaminating effluvia, or infected atmosphere, productive of the more violent states of puerperal diseases, and the sources from which such effluvia proceeds, cannot be disputed; but its modes of invasion and operation are not quite so manifest. I believe, however, from what I have observed in the different circumstances in which this effluvia or contaminated atmosphere has been generated, that its modes of invasion and operation differ materially according to the concentration of this cause, and to the circumstances favouring its invasion in one way in preference to another. Thus, in the more concentrated state of the effluvia, as generated in the crowded wards of a lying-in hospital during a cold and humid state of the air, and when due ventilation was prevented, I have seen females without any complaint, and dead within twenty hours afterwards; and on dissection neither the uterus nor its appendages, nor the peritoneum, has presented any manifest lesion, or any change more evident than that of other organs; the chief alteration being a fluid and dark state of the blood, some congestion of the lungs, and enormous flatulent distention of the elementary canal. (See hereafter.) In these cases, which were observed as closely as I was able, I attributed the intensity of the operation of the poison to its being respired with the air, to its operation on the nervous system and blood, to its contaminating the fluids, and to its impairing not only the crasis of the blood, but also the vital cohesion of the tissues, as evinced upon dissection, even before the body had entirely cooled.

39. In other circumstances, when the morbid or poisonous effluvia appeared to be less concentrated, and to be productive of a less malignant or less rapidly fatal disease, and where there was less crowding, and better ventilation of the wards, the effects were different both as to their procession and as to their issue. The appearances after death were varied, and were most remarkable in the peritoneum, or in the uterus, or in the uterine sinuses, or in the veins of the uterus and its appendages; and, in respect of these cases, I have doubted whether or not the poisonous effluvia or emanation had invaded the frame through the respiratory organs, or by the vulva and vagina, or by both avenues. It may be viewed as a somewhat extravagant notion to suppose that an agent disseminated in, and conveyed by, the air can contaminate or infect the frame by the latter avenue—by the vagina. But if the effects of the admission of even pure air into the cavity of an abscess, and the difficulty of preventing this admission on occasions of opening psoas and lumbar abscesses, and of puncturing empyema, be duly estimated, the probability of air finding admission by the vagina to the uterus will be admitted, especially when the states of these parts for some days after parturition is considered. If, then, the air already poisoned or contaminated thus finds its way into either the vagina or the uterus—an avenue much more

patent than the opening into a chronic abscess, &c.—it will necessarily occasion, in the puerperal state, effects even more remarkable than when admitted into other cavities; for the already infected air will contaminate not only the discharges retained in these situations, rendering them still more injurious and infecting, but also the surfaces with which they come in contact, and which, as respects the uterus, resemble those of a recent wound, and, as regards the vagina, are excoriated, tender, or inflamed.

40. If the production of dangerous states of puerperal disease by this local contamination be admitted, the very intimate connexion between certain forms of puerperal fevers and erysipelas will be farther demonstrated thereby; while, on the other hand, this admitted connexion between these maladies will evince the high probability of this mode of infection and contamination. It is extremely probable, moreover, that the vital depression produced by the foul air respired by the puerperal female, or even by an infecting effluvia communicated by the clothes of an accoucheur, will so influence the state of the recently-delivered uterus as to give rise to farther changes: 1st. To imperfect contraction of the uterus and impaired tonic action, and to the slow return to the natural states of the vagina and vulva; 2d. To an altered, contaminating, or morbid state of the lochia; 3d. To a more marked disposition to the absorption of such parts of this altered discharge as may be retained in the uterus or vagina; and, 4th. To the prominent changes observed after death in the uterus, its appendages, and peritoneum.

41. VI. THE CAUSES OF THE SERIOUS NATURE OF ALL, AND THE VERY DANGEROUS TENDENCY OF SOME, PUERPERAL DISEASES, will readily appear from what I have already advanced respecting the changes experienced by the female frame in connexion with the puerperal state, and the nature of the influences and agents to which the female in this state may be exposed. The shock which the vitality of the frame has received during parturition, its manifest effects on the nervous system of some females; the predisposition to fever, mania, or convulsion which it occasions; the sudden removal of distention and of pressure; the as sudden change in the state of the vascular system, as respects both fulness or deficiency, and distribution or determination of blood; the continuance of weakening discharges and of depressing mental emotions; the alterations in the secretions and excretions; and the organic disposition of the sexual organs and adjoining tissues and viscera to experience structural change during the puerperal states—all and severally tend to impart a serious or dangerous character to the diseases which occur during these states.

42. But it is not only to the changes which the female constitution undergoes in the puerperal states that the severity of the diseases incidental to those states are to be imputed, but also to the nature of the causes which produce these diseases, and to the pathological changes which necessarily follow, if they be not arrested by prompt and active measures at an early period of their progress, and before the fluids become contaminated, and the predisposed structures disorganized or altered. The diseases, also, with which puerperal females

are affected, whether those following the operation of the common or physical causes, of those induced by the imbibition and absorption of morbid secretions or excretions, or by infectious effluvia, are seldom simple or uncomplicated—are not confined to the nervous system, or to the vascular system, or to the sexual organs, or even to several of the abdominal viscera—but extend to all the general systems, implicate both the nervous and vascular systems, change the vital and physical conditions of the blood, and affect, in a more or less prominent manner, the generative organs and peritoneal surface, which in many cases manifest the greatest amount of organic lesion. It is obvious that diseases of so complicated and general a character, affecting the chief factors of life, changing the conditions of vital fluids and of vital organs, attacking the frame at that period of existence, and in that condition, which are the most liable and open to their invasion, and in which the vital energies are the least capable of resistance, will, in these circumstances, make a rapid, a dangerous, and often a fatal progress.

43. VII. OF THE PREVENTION OF PUERPERAL MALADIES.—The remarks which I have offered above on the management, both of the natural course of convalescence after delivery and of the slightest deviations from it (§ 26–34), and on the chief causes of the most important of puerperal diseases (§ 35, *et seq.*), will have already shown what the chief means of prevention are, and that they should have strict reference to the management of convalescence and to the treatment of those early deviations, as well as to the careful avoidance of those more noxious causes to which puerperal females may be exposed. Indeed, an early and judicious treatment of the slightest deviations from the usual progress of convalescence, and avoidance of the infectious or contaminating causes, constitute the chief means of prevention that can be adopted. Yet there are certain of these causes, and more especially of the sources whence they spring, which receive insufficient attention, and until lately have received no attention at all, even from those who consider themselves expert beyond all others, especially in matters which they view as their own particular province, and as being above all the rest most important. I believe that the chief sources of puerperal fevers, particularly of their more malignant forms, are lying-in hospitals, in which not only a very large proportion of those who are received become infected, but also from which the infection is carried abroad, not solely by the females who go out, but also by the clothes of the dead and of those who recover, and by the persons and clothes of the medical attendants. The charitable would much more wisely and humanely contribute their bounty for the promotion of cleanliness and comfort in the chambers of the poor, and for enabling the objects of their bounty to be delivered in their own houses, with requisite and healthful appliances and aids, than in causing them to be transported to sources of contamination, contingent infection, and in no very small proportion, even of death.

44. The importance of removing, and of avoiding, when removal cannot be attained, the several sources of infectious effluvia which have

been mentioned under the several heads already referred to, was not the less obvious because it was so generally overlooked previously to the appearance of those parts of this work in which the injurious effects of these sources of contamination were treated of; and even now they have not received the least attention as respects their influence in causing the more important maladies incidental to the puerperal state. The nature, the number, and the concentrated agencies of these sources are now too manifest to require description; but there is at least one to which insufficient attention—or, indeed, no attention at all—has been directed, namely, the impure state of the *bedding* used by many persons of the middle classes, and of those below them, although not the poorest. The beds, consisting chiefly of feathers or wool, always of animal substances—having imbibed the effluvium and perspiration of the persons who have slept on them during many years, or even during generations, without having once undergone purification—have become more or less contaminated by the continued use; and it cannot, therefore, be a matter of surprise if, in certain occasions of prolonged occupation, and in some atmospheric conditions, an effluvium should be evolved from them productive of infection or contamination to the susceptible and predisposed puerperal female. That a contaminating effluvium is actually evolved from foul beds in these circumstances, I believe, because I have seen proofs of this cause of dangerous disease; and hence more notice should be taken of this source of human, and especially of puerperal infection, than it has hitherto received. It is not improbable that puerperal females are not the only sufferers from this cause, and that puerperal fevers are not the only diseases which may occasionally originate in this source, but also that erysipelas, typhoid fevers, and other febrile and infectious maladies may often be produced by the same causes, both in the wards of an hospital, and in the close and impure sleeping apartments and beds of the poorer classes, and even of those next above them, when the infection becomes more generally diffused.

45. II. OF THE LOCAL AND FUNCTIONAL DISEASES INCIDENTAL TO THE PUERPERAL STATE.—Several of these diseases are treated of under distinct heads. *Phlegmasia dolens*, *puerperal convulsions*, *uterine hemorrhages*, and *puerperal mania* have separate articles assigned to them. (See *arts. CONVULSIONS*, § 27, *et seq.*; *HEMORRHAGE*, *UTERINE*, and *INSANITY*, *PUERPERAL*). The disorders incidental to the *mamma* and to the secretion of *milk* are considered in the articles *LACTATION* and *MAMMÆ*. It therefore only remains for me to notice at this place certain *lesions* of the sexual and adjoining organs which are apt to occur, during and subsequent to parturition, and the *fevers* to which puerperal females are liable.

46. i. STRUCTURAL LESIONS CONSEQUENT UPON PARTURITION.

CLASSIF.—IV. CLASS, IV. ORDER (*Author*).

47. A. SANGUINEOUS TUMOUR OF THE VULVÆ. *Sanguineous tumour of the labia*, CHURCHILL.—*Sanguineous extravasation into the labia*, CROSSE.—*Effusion of blood into the cellular tissue of one or of both labia* is of rare occurrence. It has been observed and described by MACBRIDE, MAIT-

LAND, DENMAN, BURNS, MERRIMAN, DEWEES, HAMILTON, CROSSE, and others.

48. The effusion may not be limited to the vulva, but may extend into the pelvis, and downward to the perinæum. It may occur during labour, previously to the delivery of the child, as in Dr. MAITLAND's case, but much more frequently immediately afterward. The tumefaction is generally sudden, and increases rapidly. The size varies much, and has even reached that of a child's head. Dr. CHURCHILL, quoting M. SCHEDEL, states, that as much as six or seven pounds of blood have escaped.

49. a. It is caused by the rupture of some vessel or vessels, by the pressure of the child's head while passing through the pelvis; and most probably the ruptured vessels have been in a varicose or disordered state previously. "Dr. BURNS supposes some of the vessels of the nymphæ to be ruptured; Dr. DEWEES, that the vessels of the vagina give way; and Drs. DAVIS and CAMPBELL, the pudic vein." But there is not sufficient reason to assign it to any particular vessel. It most probably arises from the rupture of several small varicose veins. This lesion has usually followed natural labours.

50. b. *Symptoms*.—The patient's attention is first directed to it by the swelling of the labia, and by a sense of weight and of bearing down. On examination, one or both labia are found distended, sometimes enormously, and the labium everted, so that the tumour appears partially covered by the mucous membrane. The colour is livid, or nearly black. The parts are extremely tender, and the pain is very great. The tumour increases rapidly until it covers the vulva and the perinæum. Dr. CHURCHILL states, that a considerable degree of fever is present; the pulse becomes quick, the skin hot, and the head pained; there is sometimes, also, delirium. Retention of urine, from the pressure of the tumour on the orifice of the urethra, increases the distress. The patient lies on her back, scarcely able to move, with the thighs widely separated, unable to bear even the pressure of the bed-clothes (DEWEES). After a few hours, relief is obtained by the rupture of the labium, which always takes place on its inner surface, and by the discharge of blood. A small portion of this surface begins to slough, and part of the blood escapes; but, some coagula remaining, the wound becomes offensive from their decomposition. The slough and remaining coagula are afterward thrown off, and the parts generally heal by degrees.

51. The rupture of the tumour rarely takes place during the labour; but in this case, as well as in others where it occurs before the blood is coagulated, the hemorrhage is so great as to occasion fainting, or even death, as in the instances adduced by PHILLIPART, CROSSE, NÆGALÈ, SCHEDEL, and others. If the tumour be very large before the birth of the child, it proves so serious an obstacle as to require surgical interference. This tumour cannot be mistaken for *hernia*; the rapidity of its appearance, the period of its occurrence, its size and colour sufficiently distinguishing it from *hernia*. It has been mistaken for the distended membranes, and punctured with this idea; but the bag formed by the membranes can be isolated from the labia and traced up to the os uteri. Besides,

this tumour generally does not occur until after delivery.

52. *c.* The *treatment* is evidently to give as early an issue as possible, after the blood has coagulated, to the contents of the tumour. If the risk of hemorrhage before coagulation be considered so great as to prevent an opening being sooner made in the tumour, the urine ought to be drawn off, and an enema, with an ounce or an ounce and a half of oil of turpentine, administered. In no case should this enema be withheld, and rarely ought an incision into the labium be delayed longer than two or three hours. When the small coagula infiltrating the cellular tissue causes an offensive discharge, then lotions with vinegar, water, and creasote, or with chloride of lime, or ehareal poultices, may be employed. If hemorrhage continue, or return, the turpentine elyster should be repeated, and compresses, moistened with oil of turpentine, applied. The bowels ought to be kept open, and the febrile and other symptoms treated according to general principles and the peculiarities of the case.

53. *B. LACERATION OF THE PERINÆUM.*—This accident is varied in extent. Where it is slight, it may not materially interfere with the comfort of the patient, but when it is extensive it is a cause of almost constant distress. It occurs most frequently during first labours.—*a.* "The exact *situation and extent* of the rupture vary with the cause and the circumstances of the case. 1st. It may commence at the anterior border and extend to the sphincter ani, and this is the most frequent extent. 2d. The rent may involve the entire perinæum, and extend through the sphincter ani, laying the cavities of the rectum and vagina into one. 3d. The central space of the perinæum is sometimes ruptured, leaving the anterior edge and the sphincter ani untouched." Both the child and the placenta may pass through this central laceration, or completely *per anum*. 4th. The recto-vaginal septum, sphincter ani, and part of the perinæum may be torn, so as to permit the passage of the child, leaving the anterior portion of the perinæum entire.

54. *b.* The *causes* are deviations from the ordinary mechanism of parturition; malconformation of the passages, or of the soft parts; exostosis or tumours in the pelvic cavity; excessive violence of the pains, and the too rapid passage of the head of the fœtus; great breadth, or extreme rigidity, or great weakness of the perinæum; malposition of the child's head, or malpresentations; and mismanagement or want of care, especially when instruments are used. Thus it will appear that this accident cannot always be prevented.

55. *c.* The *symptoms and consequences* of laceration depend upon the extent of it. If the injury be slight, no ill effects may probably result; but if it extend to the sphincter, the patient complains of want of support, and is liable to proclivita of the womb. If the recto-vaginal septum be torn, the state of the patient is most distressing. The fœces, for some time at least, pass through the vagina involuntarily; and the utmost attention to cleanliness is required, but cannot always prevent most distressing annoyances. When slight, the rent commonly contracts, and heals without interference, after a short time. Even when the

recto-vaginal septum is torn, partial union may take place, and leave only a fistulous opening. Dr. Burns remarks, that a valve may ultimately be formed, so that the patient may be partly relieved of her infirmity. But frequently the lochial discharge passing over the wound prevents the natural process of cure, and the torn surfaces become callous, or degenerate into ulceration in consequence.

56. *d.* The *prevention and treatment* of this accident are fully discussed in works on midwifery and surgery. To these I must refer the reader. But I may remark, that slight cases require only cleanliness: the part will heal of itself, and the patient may not even suspect what has occurred. Even when the laceration is more considerable, all that may be required is, to give at first one or two active purges, and afterward allow the bowels to become costive, to observe strict cleanliness, and to keep the patient in one position, so as to preserve the edges of the wound in contact. If these means do not succeed, a binder may be passed around the hips, and a pad on each side of the perinæum, so as to preserve the edges of the wound in apposition. Sutures of different kinds have been employed, and have succeeded in rare instances. After sufficient purging, it may be advisable to give opiates, so as to cause costiveness for a few days, and thereby to aid in the restoration of the parts. The catheter must be passed twice or thrice daily, and means used to absorb entirely the discharge. The *diet* should be spare, and chiefly farinaceous. Perfect quietude is necessary. In the various circumstances in which a failure, partial or complete, of the above means may occur, the assistance of the surgeon and mechanist will be required.

57. *C. RUPTURE OF THE UTERUS AND VAGINA.*—This fatal occurrence may take place during parturition, during pregnancy, and at an advanced period of life, of course unconnected with pregnancy; this last being the rarest. Dr. CHURCHILL adduces statistical details of this accident, from which it appears that Dr COLLINS met with thirty-four cases out of 16,654; that sixty-five cases occurred in an aggregate of 42,768 patients, or about one in 657. Dr. Burns says, that it happens about once in 940 cases. It is not so often met with in first as in subsequent pregnancies. Of seventy-five cases, nine occurred in the first pregnancy, fourteen in the second, thirteen in the third, and thirty-seven in the fourth and subsequent pregnancies.

58. *a. Causes.*—1st. *During gestation*, it may arise from that form of extra-uterine pregnancy called *interstitial fœtation*; the ovum being retained, in passing the Fallopian tube into the uterus, between the uterine fibres, where, as it grows, it occasions the absorption of that portion of the uterine parietes, which at last give way, and allows the fetus to pass into the abdominal cavity. Rupture of the uterus may also proceed from disease, as from inflammation, softening, or suppuration of a portion of the walls of the organ; or it may be produced by accidents, blows, falls, &c. It may even occur without any assignable cause, unless it be then occasioned, as Dr. Burns supposes, by irregular action of the fibres of the uterus.

59. 2d. *During parturition*, it may also arise from pre-existing disease, and especially from

any one of the usual consequences of inflammation. A portion, also, of the uterus may be atrophied, softened, or thinned by the pressure of the child against it, or by pressure of some part of the abdominal or pelvic parietes, so as to yield during the uterine contractions of parturition. DEPARQUE mentions scirrhus of the uterus as one of the causes of rupture; but this is doubtful. When partial inflammation of the uterus has existed during gestation (§ 58), then the laceration has usually corresponded with the situation of the previous pain marking the seat of inflammation. There can be no doubt that a perfectly healthy uterus is rarely or never ruptured. In one case M. MALGAIGNE attributed the rupture to the administration of ergot of rye.

60. *b.* The period of labour at which rupture may occur varies; "it may be at the beginning, before the rupture of the membranes; during the passage of the head through the pelvis; or in the moment when the child is delivered." Narrowing of the upper outlet may give rise to it; or any other mechanical obstacle opposing the actions of the uterus; or even oblique positions of the womb. The age of the patient has but little influence in predisposing to rupture.

61. *c.* The rupture may only be *partial*, some one of the tissues of the uterus giving way either previously to or during labour, probably owing to antecedent disease, or to peculiarity of structure. The peritoneal coat alone may be torn, or the muscular coat may be ruptured, the peritoneal covering remaining uninjured. Dr. COLLINS met with nine cases of this description. Although the extent of lesion is less in such instances, yet Dr. CHURCHILL considers it to be equally fatal. And as in other forms of rupture, it may be caused by external injuries, by excessive movements of the child, by overdistention, &c.

62. Violence in turning the child may cause rupture; "and it may accompany this operation, in certain states of the cervix uteri, without any fault of the operator." Rigidity of the os uteri, or imperforation, may also occasion laceration. Several instances are recorded in which the os uteri was torn completely off during labour. Pressure at the brim of the pelvis, rendering the cervix uteri thinner or softer than natural, and more easily torn, has been assigned for this occurrence.

63. *3d.* At an advanced period of life the structure of the cervix uteri is more or less changed, becoming dense, cartilaginous, and the canal reduced in size, or even obliterated. The outlet for the escape of secretions accumulated in the uterine cavity is thus closed; and if the quantity collected be sufficient to distend the organ, some portion of the walls experiences absorption and thinning, or inflammation and softening. Thus an opening or perforation may be made by absorption, or by rupture, into the peritoneal sac.

64. *d.* On dissection, the torn edges, and the parts immediately adjoining, usually exhibit marks of disease when the rupture has proceeded from this cause, the laceration in such cases occurring in any part of the organ. "When the rupture is the result of mechanical causes, it generally takes place near the cervix, and involves both the uterus and vagina,"

the part which gives way being usually near the union of the cervix with the vagina. The wound is commonly transverse. Of twenty-three cases, Dr. COLLINS found one on the right, one on the left side, eleven posteriorly, and ten anteriorly. The structure of the uterus is hardly altered—is firm in texture, and natural in colour, except a few ecchymoses. The edges of the laceration are jagged or uneven. In very rare instances the bladder has also been ruptured. When the *peritoneal surface* of the uterus has alone been torn, several small lacerations, resembling scarifications, from a quarter to half an inch in length, and one or two lines in depth, are found. They are attended by the effusion of blood in the peritoneal cavity, and by the usual appearances and products of peritonitis, which are caused by the effused blood and the injury. When the *muscular substance* is alone torn, there may or may not be found evidence of pre-existent disease. The peritoneal covering is generally inflamed, and blood is found effused in the cavity of the uterus. Laceration of the *cervix uteri* is accompanied with a bruised appearance; its edges are ragged and uneven, and the parts immediately adjoining red and swollen. The connexion between the cervix and vagina is not compromised. In cases of rupture of the uterus in *old persons* (§ 63), the viscus is rather perforated than ruptured; the changes caused by the contents, and the softening and thinning of a portion of the parietes, appearing more like perforation than rupture. *Peritonitis* always follows rupture of the uterus if the patient survive the shock.

65. *e.* *Symptoms.*—The symptoms vary somewhat with the extent of the rupture, according as the peritoneal or the muscular coat is singly torn. The circumstances which may suggest fears of rupture are the occurrence of partial inflammation of the uterus during gestation, and the existence of violent labour-pains in patients with a narrow or mal-formed pelvis. "Rupture of the uterus and vagina is marked by an acute, sudden, and intolerable pain like cramp; a sense of some part bursting, giving way, or tearing, with an audible noise, according to the testimony of the patient; the suspension of the labour-pains; hemorrhage from the vagina; and by a rapidly succeeding state of collapse." (CHURCHILL.) All these symptoms may not be observed in some cases, but the pain and collapse are never absent. When one of the coats alone is torn, the labour may continue if it be the peritoneal coat, and there may be no hemorrhage. In such cases, Dr. RAMSBOTHAM remarks that the symptoms of actual rupture of the uterine structure are observed in a diminished degree, excepting the escape of the child.

66. Rupture of the uterus is always attended by continued and extreme pain; nausea and vomiting supervene—at first of the contents of the stomach, then of a greenish, and lastly of a dark or coffee-ground-like matter; the countenance becomes pale, anxious, and ghastly; the surface and extremities cold and clammy; the pulse rapid, small, and weak, or fluttering and irregular; respiration is hurried, panting, and anxious, with a desire of fresh air; and hemorrhage takes place from the vagina, varying much in quantity. The shock or collapse character-

izing these cases is owing more to the nature and severity of the injury than to the amount of hemorrhage which may follow, although this is sometimes very considerable; but both conditions contribute to this result. When the rupture is complete, the child passes through the opening into the abdominal cavity, either partially or wholly, where it may be felt through the abdominal parietes, and the efforts at expulsion cease. If the presentation was within reach before the accident, it cannot now be ascertained. Dr. CHURCHILL refers to instances of a loop of intestine having passed through the rupture when complete, and become strangulated. The state of collapse may continue for some time, if it do not prove fatal. But at length reaction takes place to a certain amount, and the usual symptoms of peritonitis appear: exquisite tenderness, pain, and flatulent distention of the abdomen; pulse small, hard, rapid, and, lastly, weak; decubitus on the back, with the knees drawn up; hurried respiration, anxious and collapsed countenance.

67. *f. The terminations of ruptured uterus are, 1st. Death a few hours after the shock, or after delivery; 2d. Death from peritonitis; 3d. Death from consecutive lesions; and, 4th. Recovery.* In by far the greater number of instances the accident proves fatal. The aggregate of cases observed by SMELLIE, J. CLARKE, MERRIMAN, M'KEEVER, RAMSBOTHAM, COLLINS, and BEATTY, amounting to sixty-eight, furnished only six recoveries. OSIANDER, VELPEAU, and CHURCHILL quote several cases of recovery; but instances are very rare in which recovery has taken place when the fetus has remained in the peritoneal cavity. (DUPARCQUE.) In cases of interstitial foetation, also, patients have very rarely survived both shock and consequent inflammation. In all cases, therefore, of ruptured uterus the prognosis is very unfavourable.

68. *g. Diagnosis.*—The sudden and acute pain, the cessation of labour, the collapse, and the recession of the child, sufficiently indicate the nature of the mischief. When, however, the rupture is partial, the diagnosis is much more difficult. The sudden pain, collapse, and consequent peritonitis are the chief symptoms of rupture of the peritoneal coat; the pain, collapse, cessation of uterine action, and vaginal hemorrhage being the principal indications of rupture of the muscular coat. The sudden occurrence of peritonitis in *old women* may excite suspicions of perforation or rupture of the uterus, but certainty can be arrived at only by a *post-mortem* inspection.

69. *h. Treatment.*—When rupture of the uterus is recognised, the propriety of immediate delivery cannot be disputed. Common sense and experience, as evinced by the results of recorded cases, support this practice. When the os uteri is undilated, instant delivery cannot be effected; but the measures to be adopted on this emergency, as well as in others connected with the delivery, especially when the child has passed through the rent into the abdominal cavity, come not within the scope of my work. The means which should be administered during the continuance of the vital shock, or collapse, are camphor, ammonia, and opium, in such doses as may be just sufficient to support the powers of life without inducing inordinate reaction. If peritonitis supervene, calomel,

camphor, and opium; terebinthinate embrocations applied over the abdomen; opium in large doses, and the other means recommended in cases of inflammation of the PERITONEUM (§ 138, *et seq.*), should be prescribed, bearing, however, in recollection that the large loss of blood usually occasioned by the rupture, as well as the shock sustained by the vital powers, prevents either depleting or depressing measures from being too freely employed.

70. *D. INFLAMMATION OF THE VAGINA.*—Inflammation of the vagina may occur independently of the puerperal state, or it may arise from specific causes, or infection, as shown in the article VAGINA.—(a) It is of frequent occurrence after delivery, in various grades of severity. It may consist merely of slight soreness or excoriation, or irritation, and follow an ordinary or natural labour, and speedily subside, unless it be prolonged or exasperated by an acrid state of the lochia. When, however, the head of the child has remained a long time in the pelvis, pressing on the soft parts, or when the narrowness of the passage has created great difficulty, or when the presentation has been unnatural, or when instrumental aid has been required, the vagina is then liable to experience most severe inflammation, the consequences of which may be most serious.

71. (b) The symptoms generally commence with a smarting pain, more severe than that usually following delivery, soon passing into a sense of painful heat and scalding, extending from the external parts up the vagina. There is also a feeling of fullness and weight in this situation. On examination, the external parts appear swollen and bruised, with increased heat, and acute pain or tenderness, when touched. On averting the labia, the vagina presents large rugæ of a bright red colour. At first the discharge from the inflamed surface is scanty, but it afterward is purulent, or pus may be detected, mixed with the red lochial discharge. If the discharge have become more colourless, the puriform secretion from the vagina renders it more opaque. With the local increased action more or less of symptomatic fever is present; and in the more severe cases this fever may assume a very serious aspect.

72. (c) The terminations are sometimes serious. The slighter cases, or those which receive prompt and judicious treatment, usually terminate in resolution. The decrease of pain, and of the local and constitutional symptoms, is the chief indication of this issue. Suppuration and ulceration are not infrequent. When the injury causing the inflammation has been severe, or the attack violent from the first, suppuration advances rapidly, is attended by a copious puriform discharge, and, in the course of a very few days, is followed by the appearance of a number of sloughing ulcers, or, rather, of several partially detached portions of sloughing mucous membrane. As these separate, the parts which they covered appear deprived of membrane. If the sloughing ulceration be more severe, the coats beneath the mucous coat may be invaded; and it is then not uncommon to find the posterior part of the neck of the bladder attacked, and even an opening formed in this situation—a *vesico-vaginal fistula*; or to find a similar sloughing ulcer into the rectum—or a *recto-vaginal fistula* to be formed. When slough-

ing ulceration appears, the greatest care may not succeed in preventing these consequences from occurring.

73. *Gangrene* may rapidly follow when the pressure on the parts has been prolonged or excessive. In these cases the separation of the sloughs is generally followed by vesico-vaginal fistula; more rarely by recto-vaginal fistula. In 1845, a lady who had experienced the most unaccountable neglect while in the care of a surgeon in the East Indies, but who was perfectly well formed, came to London for the advice of the author and the late Mr. LISTON. Most extensive recto-vaginal and vesico-vaginal fistulae co-existed in her case. She had been a strong and healthy person previously to her protracted confinement in the East. When she came to London, the urinary bladder, the vagina, and the rectum formed a single cavity. The case was far beyond any measures, excepting mechanical aids, and strict attention to cleanliness.

74. (d) *Treatment*.—The usual antiphlogistic means, appropriate in kind and extent to the violence of the inflammation, and the habit of body and constitution of the patient, are required at an early stage. Dr. CHURCHILL has found *tartar emetic*, conjoined with a saline aperient, of great use. It should be given so as to nauseate without producing vomiting. "The external parts ought to be well fomented two or three times a day; and, during the intervals, a large poultice may be applied over the vulva. Twice or thrice daily, also, the vagina should be syringed with tepid milk and water, or a weak solution of acetate of lead. After the sloughs have separated, a careful examination should be made every second day, to ascertain the progress of healing; and when the surfaces begin to be covered with new membrane, we must take measures for preventing the formation of cicatrices. This can be done only by the repeated introduction of bougies, and the best kind are tallow or wax candles. At first a small-sized one should be oiled and introduced night and morning, and allowed to remain a quarter of an hour. Afterward, as the tenderness diminishes, the size of the candle should be increased; and it ought to be introduced oftener and retained longer. The warm injections should be continued, and the milk and water may be changed for some slightly astringent fluid." (CHURCHILL, *Op. cit.*, p. 281.) When sloughing ulceration or gangrene exists, a restorative or tonic treatment, and light, nutritious diet, are required. The unfavourable consequences of these changes—*vesico-vaginal* or *recto-vaginal fistula*—are sometimes remedied, when not very extensive, by surgical treatment. For the measures which may be attempted for these distressing lesions, I must refer the reader either to surgical works, or to the systems of midwifery practice referred to hereafter, and more particularly to Dr. CHURCHILL's work. (See art. VAGINA for other lesions not necessarily proceeding from the puerperal state.)

75. *E. INVERSION OF THE UTERUS*.—*The inside of the uterus may be turned out, and either drawn or pushed down into the vagina.* It may take place in different degrees, and form what has been called, 1st. Simple depression; 2d. Incomplete inversion, when the fundus uteri is

merely engaged in the orifice; and, 3d. Complete inversion, when it protrudes from the vagina, with the mouth turned upward. The vagina, in this latter case, is also partly reversed, so that the tumour is often of considerable length. When the inversion is only partial, the tumour is retained altogether, or chiefly within the vagina, the fundus protruding in part through the os uteri.

76. (a) *Symptoms*.—The patient with inversion of the uterus feels severe and obstinate pain, accompanied with bearing down efforts, by which a partial inversion is sometimes rendered complete. She is very weak; her countenance is pale and anxious; and her pulse is feeble, small, or almost imperceptible. Hemorrhage is generally present, and is often most profuse. It is frequently scanty, or absent, when the inversion is complete; although a very partial inversion may be attended by a fatal discharge. A sense of dragging at the epigastrium, or of a dragging downward of the bowels, is usually present; and fainting and convulsions may occur even when the hemorrhage is trifling. These symptoms cannot fail of exciting suspicions of inversion, which will be readily ascertained on examination; the womb protruding like a mass of flesh, and no uterine tumour being present in the hypogastrium.

77. (b) *Causes*.—Inversion is produced by pulling the cord in endeavours to remove the placenta, which may even adhere when the uterus is pulled down; but it is generally separated; or it is caused by the sudden expulsion of the child, the cord being short or entangled about the child, the fundus receives a jerk, and is thereby inverted. Dr. BURNS thinks that great pressure or strong contraction of the abdominal muscles on the fundus uteri may cause depression of the fundus, in a cup-form, and encroach on the uterine cavity. This may rectify itself, but it may increase and pass on to complete inversion some time after delivery. An incomplete inversion, as well as the complete, may become chronic, and occasion incurable fluor albus, and even hemorrhage.

78. (c) *Inversion terminates* in different ways: it may be rapidly fatal by hemorrhage, or by syncope, or by convulsions; or it may be slowly fatal by inducing over-distention of the bladder, or inflammation, and various consequent changes. After severe pains and expulsive efforts, the patient may survive, or even partially recover, from the immediate injury; the uterus may slowly diminish to its natural size, become *chronic*, and cause little inconvenience; or it may discharge fetid matter, and give rise to frequent debilitating hemorrhages, with copious mucous discharge in the intervals; or hectic or pulmonary symptoms may come on, and the patient ultimately sink.

79. (d) *The treatment* consists in reducing the inversion, if it be discovered sufficiently early. This is to be done by first pressing the uterus, if it have protruded without the vagina, within this passage. The tumour should be grasped cautiously in the hand; and, while it is compressed, the most prominent part of the fundus ought to be pushed up in the direction of the axis of the uterus. If reduction is accomplished, the hand should be kept within the uterus, so as to excite contractions, which will

detach the placenta, if it still adhere. Even after the reduction, when the patient is apparently doing well, she may be seized with a fit, and die. But she generally remains long weak if she recover.

80. If inversion have not been early discovered, it is always much more difficult, and sometimes impossible, to reduce it. The obstacle is the contracted state of the os uteri. It may not admit of reduction, even after a few hours from its occurrence; and if it have become much more chronic, it is not prudent to make the attempt, as violent or dangerous convulsions may be produced thereby, and the uterus is often so swollen and inflamed as to render reduction impossible. The *chronic state of inversion* is considered under the head UTERUS, as it does not strictly belong to puerperal maladies.

## II. THE SPASMODIC AND NERVOUS AFFECTIONS OF THE PUERPERAL STATE.

### CLASSIF.—II. CLASS, III. ORDER (Author).

81. The nervous and spasmodic diseases of puerperal females are *convulsions*, *mania* or *insanity*, *hystericalgia*, *paralysis*, and various irregular *spasmodic* and *nervous affections*, which seldom assume any precise or definite form. The first and second of these are considered in separate articles; the others will be briefly noticed at this place.

82. *A. HYSTERALGIA.*—(a) This *painful affection of the uterus* occurs soon after delivery; but it is more continued and severe than the usual *after-pains* (which see). It is characterized by severe pain in the back and hypogastrium, by sickness, faintness, and a feeble, or sometimes quick pulse. These sensations may or may not be attended by the expulsion of coagula, or by a sense of severe bearing down. It not improbably is sometimes occasioned by some malposition of the uterus consequent upon delivery. It is often connected with obstruction of the lochial discharge, which obstruction is probably caused by the painful affection of the uterus. Hystericalgia is most apt to occur after a severe or tedious labour. It may not appear until the third or fourth day, or when the patient has got up too early to have the bed made. It seems to be caused by an irregular spasmodic action of the muscular fibres of the organ, the spasmodic action and the altered sensibility sometimes extending also to the bowels.

83. (b) The *symptoms* of hystericalgia vary with the extension of these morbid states to parts adjoining the womb and its appendages. The suddenness of the attack; the absence of rigours or chills; the greater severity of the pain than that attending inflammation; the suddenness of the remission or cessation of the pain, and generally the absence of tenderness or of increased suffering on pressure, chiefly serve to distinguish this affection from inflammation of the uterus.

84. (c) The *treatment* consists of the administration of a purgative clyster with turpentine, castor oil, and camphor; and, after the bowels have been freely evacuated by these, or by a repetition of them, or by a draught containing half an ounce each of castor oil and turpentine, an opiate may be given, or may be administered in an enema. Terebinthinate fomentations or embrocations should also be applied, suffi-

ciently warm, over the hypogastrium; and warm or camphoreted diaphoretics and opium, or henbane, may be given, to equalize the circulation and procure a free respiration. Warm cloths soaked with oil of turpentine, and kept applied over the seat of pain, also will seldom fail of procuring relief. The abstraction of blood is rarely required, unless the affection be actually inflammatory, as evinced by increase of pain on slight pressure, by the states of the skin and urine, and by the pulse.

85. *B. VARIOUS OTHER NERVOUS OR SPASMODIC AFFECTIONS* sometimes appear in the puerperal state, especially in hysterical, delicate, or nervous females, and are evidently owing to the effects produced by uterine action and the vital shock upon the organic and cerebro-spinal nervous systems.—(a) *Palpitations of the heart* are not infrequent soon after delivery in the temperaments just mentioned, especially after considerable loss of blood, and upon any alarm. The patient experiences a violent beating not only at the præcordia, but also in the epigastrium and in the head, sometimes with dyspnoea, or short panting respiration. She is alarmed, apprehensive of dissolution, and her fears aggravate the symptoms. As the attack passes off, languor, depression, or a sense of sinking, or profuse perspiration, and flatulent distention usually supervene, and after a time the disorder subsides.

86. (b) *Hysteria* is not uncommon, in some form or other. It may occur with dyspnoea, or with syncope, with hiccup, or with pains in the side or abdominal muscles, &c., and is generally aggravated, if not excited, by the secretion of air into the alimentary canal. The dyspnoea is seldom attended by cough, and is owing chiefly to exhausted power of the respiratory muscles, and sometimes to either too great or too little tightness of the abdominal bandage, the abdominal muscles and floating ribs being thereby too much compressed and embarrassed in the one case, or insufficiently supported in the other. When the *dyspnoea* is owing to an affection or *spasm of the diaphragm*, it is felt most on inspiration, and pain is often complained of in the back or sides, or pit of the stomach, with a feeling of suffocation, sharp pain sometimes darting across the lower part of the thorax, and with a very rapid weak pulse. This affection of the diaphragm usually occurs a few hours after delivery, and is always sudden in its accession and departure. It may readily be distinguished from pleurisy by these circumstances, and by the slower accession of pleurisy, which is usually accompanied with shivering or chills, and which very rarely or never appears so soon after delivery.

87. (d) *Colic* may occur within a few days from delivery. It usually attacks suddenly, and in the evening; but it is not preceded by shivering, although it is sometimes attended by sickness or vomiting. The pulse is at first slow or natural, but it soon becomes frequent. The pain is remittent or intermittent, but commonly subsides altogether after some hours, when judiciously treated. If the irritating cause be not soon removed it may induce inflammation. *Cramp of the stomach*, or spasmodic gastrodynia, may occur during the first fortnight or three weeks after delivery. Its attack is always sudden, the suffering extreme

and the danger great in delicate or exhausted females. It is often attended and aggravated by flatulence. It requires decided and prompt treatment.

88. (c) Females who have been subject to the more obstinate and complicated forms of hysteria, and especially to *spinal irritation*, or to affections reflected from the spinal chord or roots of the spinal nerve, often experience various nervous disorders, either immediately after, or at more distant periods from delivery. Soon after the expulsion of the placenta they feel urgent *sinking* or debility, with a sensation and dread of flooding, although neither internal nor external hemorrhage exists. In the more extreme cases, if stimuli be not administered, the patient may suddenly die, without any other obvious cause than the *sinking* or *exhaustion* consequent on the shock of parturition. These severe cases of sinking not only may affect the weak and delicate, or those weakened by flooding, or by greater losses of blood than the state of the vascular system can well sustain; but sometimes even fat, plump, and apparently strong females may be placed in jeopardy by these attacks. In other instances, the sinking is followed by violent determinations of blood to the head, threatening phrenitis, or puerperal mania, or even passing into either, or into lethargy, coma, or apoplexy. Fat, plump, and pale females are even more liable than others to experience these dangerous forms of nervous sinking, owing to their deficiency of vital power and resistance, and the states of the blood and vascular system; and in them nervous and vascular reaction are more rare.

89. (d) Partial or even complete *paraplegia* sometimes occurs after delivery, although the labour may have been easy or natural. The head is unaffected, but pain or weight is felt in the back or loins, occasionally with retention of urine. The palsy exists in various degrees, but it generally disappears after a few weeks, when the treatment is judicious. A more severe and protracted form of partial paraplegia occasionally follows severe, protracted, or instrumental delivery. In these cases severe pain is complained of in the back and loins, with disordered secretion and excretion of urine. In most of these states of paraplegia there is either increased effusion of serum from the membranes of the spinal chord, with congestion of these membranes and of the cord itself; or, what is more probable, extreme congestion, also, of the venous sinuses external to the sheath, in the lumbar and dorsal regions of the spine. *Hemiplegia* is not more frequent in lying-in than in other females.

90. (e) *The treatment of these several affections* is generally successful if it be prompt and efficient.—a. *Palpitations of the heart* (§ 85) require the administration of antispasmodics with anodynes or narcotics—of HOFFMANN'S anodyne with small doses of opium or henbane; of the boracic acid with camphor and opium, or henbane; or with the ammoniated tincture of valerian, with either of these narcotics. When the paroxysm has been relieved by these, the antispasmodics should be conjoined with tonics and aperients, and change of air, preferably to the country or to the sea-side, ought to be recommended.

91. β. *The hysterical affections* (§ 86) are re-

lieved by the remedies just now enumerated, more especially by the ethers, valerian, ammonia or camphor, and opium; and if dyspnoea be present, the state of the abdominal bandage should be examined and adjusted. If the symptoms be aggravated by flatulence, as they often are, ammonia or magnesia may be given with anti-spasmodic stimulants and warm terebinthinate embrocations, or epithems applied over the epigastrium. When the hysterical affection assumes a *colicky* form (§ 87), from two to four drachms of oil of turpentine may be given with half an ounce of castor oil, and a drachm of tincture of senna, on the surface of an aromatic water; and the same remedies, in increased doses, administered as a clyster, if the bowels are not freely evacuated in six hours. After the evacuation of the bowels a full dose of opium, or of the compound soap pill will be given with benefit. If *flatulence* still continue, ammonia or magnesia, with gentle tonics, or the fetid spirit of ammonia or the compound galbanum pill, may be prescribed at intervals. If the colicky symptoms assume the form of *cramp of the stomach*, or severe *spasmodic gastrodynia*, the patient is placed in jeopardy, especially if it occur within a fortnight or three weeks from delivery. A draught containing a full or even a very large dose of laudanum, with camphor and ether, or with musk, or the compound spirit of ammonia, ought to be immediately given, and the warm terebinthinate embrocation, or a mustard poultice, be applied over the epigastrium.

92. γ. For those states of distressing *sinking* following parturition (§ 88), Dr. BURNS advises about thirty drops of laudanum, and afterward small doses of wine or brandy, or of compound spirit of ammonia, or ammoniated tincture of valerian, taking care not to give stimuli too freely, lest cerebral affection be thereby excited. Musk or camphor with opium is generally beneficial in these cases; and light nourishment ought not to be overlooked, as not a few of these cases arise from inanition, or the prolonged privation of requisite food and restoratives. If *phrenitic* or *maniacal symptoms* supervene, the treatment must depend upon the habit of body and strength of the patient. Vascular depletions, general or local, cold applications to the head, active purgatives, and terebinthinate enemata, external derivation and irritation, and the other measures advised for cases of *Puerperal Mania* (see INSANITY, PUERPERAL, § 55, *et seq.*) should be employed.

93. δ. The occurrence of *paraplegia* in the puerperal state requires strict attention to the urinary functions and free purging, large doses of purgatives being sometimes necessary. Cupping or leeching near the spine may be requisite. Terebinthinate embrocations may also be applied in the course of the spine, and if these prove not of service, repeated blistering or open blisters may be directed, and the other means advised when treating of paraplegia (see art. PARALYSIS, § 215, *et seq.*) may be adopted. Three cases of this disease in the puerperal state have come before me, and have proved both obstinate, and afterward associated with amenorrhœa. In one which had been of long standing, the amendment was slow. As soon as the patient is able to move the lower extremities, she should endeavour to use them as

much as possible, and persist in the use of derivatives, both internal and external, of frictions, and of rubefacients.

### III. THE Milder Fevers INCIDENTAL to the Puerperal State.

CLASSIF.—III. CLASS, II. ORDER (*Author*).

#### i. EPHEMERAL FEVER.—WEED.—PUERPERAL EPHEMERA.

94. DEFIN.—*Chills or shiverings during early convalescence from parturition, followed by headache, pain in the back and limbs, thirst, rapid pulse, terminating with profuse perspiration and cessation of fever, generally in from twenty-four to forty-eight hours.*

95. A. *Causes*.—The increased sensibility, susceptibility, and irritability of puerperal females give rise to febrile attacks upon exposure to comparatively slight causes, especially when the temperament is nervous or irritable, and the constitution is delicate. These states of *predisposition* are, however, much heightened by the changes in the vascular system, and in the blood itself, consequent upon pregnancy and parturition; and these, moreover, are associated with the predisposed conditions of the uterus, mammae, and intestines, always present in these cases. The *exciting causes* are, commonly, exposure to cold, irregularities of diet, fatigue, exhaustion, want of rest, mental emotions, inattention to the state of the bowels and indigestion, getting up, or leaving the bed, or changing the apartment too soon; accumulations of morbid secretions and excretions in the biliary organs and bowels, &c.

96. B. *Symptoms*.—On the approach of the disease the patient is languid, yawns frequently, and experiences a sense of cold in the course of the spine, and extending over the body. The chilliness may increase to shivering, with or followed by headache, pain in the back and limbs; full, irregular, and rapid pulse, thirst, and slight diminution of the milk and lochia. The bowels are usually costive and flatulent, the stomach disturbed, the tongue coated; the patient is depressed in spirits; complains of shifting pains in the abdomen, is anxious or afraid of dying; and, in the more smart attacks, she is slightly delirious at night. The face is flushed, and she has pain in the breasts and in the forehead, with throbbing of the temples, and slight soreness of the abdomen. To these symptoms a copious perspiration succeeds, and removes the fever and its attendant symptoms, the milk and lochia returning to their previous states. The attack is usually terminated in about twenty-four or thirty-six hours; and, if judiciously treated, it seldom returns; but, if it be neglected, it may assume an intermittent, a remittent, or a continued form; or it may be complicated with some visceral disease, and assume a dangerous aspect.

97. C. *Diagnosis*.—The suddenness of the attack, the irregularity of the pulse, the absence of local pain, excepting that of the head and of abdominal tenderness, the rapid succession of the different stages, and the cessation of the paroxysm in a few hours, distinguish this state of fever from true puerperal fever, from which, however, it will be distinguished with difficulty during the early stage, if all the phenomena of the latter be not duly considered. (See hereafter, § 251, *et seq.*)

98. D. *Treatment*.—During the cold stage,

warm diluents, warm flannels to the back, gentle restoratives, and external warmth are required. The states of the several functions should be carefully examined; the uterine discharge, the mammae, and the abdominal secretions and excretions demanding the utmost attention. If the tongue be loaded, or if nausea be present, an ipecacuanha emetic should be given, and its operation promoted by warm diluents. If the bowels have been, and still are confined, a full dose of calomel or of calomel and jalap should be taken. In all cases the bowels ought to be freely evacuated by these or other purgatives, as the infusion of senna and salts, &c.; and, having hastened on the hot stage, saline diaphoretics, fewer bed-clothes, and diluents should be directed, in order to procure a free perspiration, which may be kept up for five or six hours. As the perspiration declines, or at the end of that period, the patient should have her clothes changed; and gentle restoratives, especially such as may promote the secretions and excretions, ought to be prescribed, with a view of preventing a return of the attack, and of restoring the tone of the system. From two to three grains of camphor, with as much henbane, taken twice or thrice daily, and such restoratives and diet as the state of the patient will suggest, will prove beneficial. If the patient be exhausted by the attack, wine-whey, or wine and water warm, with sugar, &c., may be allowed; or the tonic infusions, or the infusion of valerian, or the decoction or infusion of cinchona may be given, with the solution of the acetate of ammonia, the ammonia being a little in excess, and the spirit of nitric ether may be prescribed. The abdominal excretions ought to be freely promoted by a combination of the compound infusions of senna and gentian, and any neutral salt, with tincture of cardamoms; and rest procured by a soothing dose of camphor (1 to 3 grs.) with opium or henbane, or with morphia. Change of air, especially to the sea-side, is always beneficial. The diet should be light and nutritious as convalescence advances. The states of the mammae and uterus should receive strict attention, and if either organ present prominent disorder, the treatment should be directed accordingly.

#### 99. ii. INTestinal OR GASTRIC FEVER.—FEBRIS GASTRICA VEL INTESTINALIS.—F. Gastrica vel Intestinalis Puerperalis; Puerperal gastro-intestinal Fever.

CLASSIF.—*Ut supra*.

100. DEFIN.—*After chilliness or shivering, fever, with nausea or vomiting, flatulence, griping, diarrhoea, and various nervous symptoms.*

101. A. This state of fever is generally caused by previous torpor of and inattention to the bowels, by accumulations of bile in the biliary organs, and of morbid secretions and faecal matters in the bowels, especially during the advanced period of gestation; by errors of diet after delivery; by close, low, damp, and cold apartments or situations; and by the use of acid, cold, or unsuitable drink or beverages. It usually appears within ten or twelve days from delivery, and is liable to be confounded with ephemeral fever at its commencement; and, when attended by inflation of the bowels, with the puerperal fevers.

102. B. *Symptoms*.—After chilliness or rigours

the patient is oppressed at the stomach, loathes food, and becomes sick. The pulse is frequent and soft; she complains of being cold, although the skin, except that of the feet or legs, feels from the first hot to another person. Afterward she is thirsty, has a slimy or white tongue, sometimes with red edges, and vomits a ropy mucus or bile. She now feels hot, especially in the hands and feet, is distressed with flatulence and griping pains in the abdomen, and the bowels are at first either open or costive, the stools dark and very offensive, and subsequently relaxed or even purged. Purgative medicines always act abundantly, and afford relief. The pulse continues quick; the patient does not sleep, or merely slumbers; and then she talks, or is tormented by visions and dreams. She often complains of short, darting, or nervous pains, or of throbbing or confusion in the head. There is no fixed pain in the abdomen or hypogastrium, nor any tumour in the belly, which is generally soft. The local discharge is not necessarily obstructed, nor is the secretion of milk affected during several days; but, when diarrhoea is considerable, or continues, both one and the other are much diminished or suppressed. The countenance is unchanged at first, and continues so for some days, unless nervous symptoms, or pain in the hypogastrium, or some complication supervene. In some cases, when this disorder continues longer than six or seven days, and is neglected, inflation of the bowels, pain and tenderness in the lower part of the belly, pain on making water, or on passing the fæces, and other indications of irritation of the sexual organs supervene; while, in other cases, various nervous symptoms, as palpitation, vertigo, a feeling of sinking, or startings, and shooting pains in the head, are complained of. The duration of this fever, which is manifestly symptomatic of gastro-intestinal irritation, or consequent upon accumulation of morbid secretions in the biliary organs, and of fecal matters in the bowels, is usually from a few days to a fortnight.

103. *C. The Diagnosis.*—Intestinal fever may be distinguished from *ephemeral fever* by not appearing so soon after delivery; by its more gradual accession, and by the manifest disorder of the stomach and bowels attending it; by the character of the evacuations and the griping or shifting pains in the abdomen; by the ready and copious action of purgatives, and the more protracted duration of the disease. It may be mistaken for either *puerperal fevers*, but the symptoms just enumerated, the relief obtained from purgatives, the softness of the abdomen, and the absence of fixed pain, of tension and of inflation, unless occasionally in very protracted cases, the state of the pulse, and the general condition and appearance of the patient will distinguish this complaint from the more serious fevers of the puerperal state.

104. *D. Treatment.*—An emetic of ipecacuanha is always serviceable on the accession of, or early in this complaint. When its operation is over, saline diaphoretics and tepid diluents are then beneficial. A full dose of calomel may be given in a few hours after the emetic, and its operation on the bowels should be promoted by the administration of rhubarb and magnesia, or by a single dose of castor oil with spirit of turpentine. If the evacuations still

continue offensive, with griping pains, either of these purgatives should be repeated; but if they be more natural, or if diarrhoea supervene, then the existing irritation ought to be allayed by opiate or anodyne enemata. The bowels should never be allowed to become costive; either of the purgatives just named, or the infusion of gentian and senna, being interposed, or given according to the requirements of the case. If griping pains or flatulence, or inflation of the bowels become troublesome, the application of the warm terebinthinate embrocation over the abdomen, and an enema containing spirit of turpentine, with olive oil and asafoetida, will afford complete relief. The diet should depend upon the state of the bowels. If diarrhoea exist, light farinaceous articles of food, arrow-root, sago, and jelly may be given. If there be no diarrhoea, ripe fruit may be allowed; and, as convalescence proceeds, the several farinaceous articles, various preparations of rice, beef-tea, warm jellies, chicken-broth, &c., may be taken. Ginger-wine with water, Seltzer water with old Madeira or Amontillado sherry, the milder tonics, as the infusion of columba or of cheyreita, may also be prescribed as recovery proceeds.

105. *iii. MILIARY FEVER—FEBRIS MILIARIS—FEBRIS MILIARIS PUERPERALIS.*—The eruption described under the head *miliary eruption* sometimes occurs during the puerperal state as a symptom of puerperal fevers. By several older writers, and by some as recently as the last century—by WHITE and others—it was described as one of the most formidable epidemics of child-bed; but it is now rarely met with, unless occasionally as a symptom of ephemeral fever, of milk fever, and of puerperal fever, when they are attended by profuse perspiration, and is evidently dependent upon a morbid state of the circulating fluids, consequent upon imperfect secretion and excretion, or upon the absorption of morbid matters, in connexion with excessive secretion from the skin. It occurs most frequently in delicate females, and commonly from the fourth to the twelfth day from delivery. This eruption affords no crisis to the disease of which it is symptomatic, nor relief to the symptoms. The treatment of this eruption, or, rather, of the disease of which it is a symptom, should be directed to the pathological conditions of that disease, as stated in the article "MILIARY ERUPTION."

IV. SEVERE PUERPERAL FEVERS.—SYNON. *Puerperal Fevers.*—*Febris Puerperalis; Febris Puerperarum; Metritis Puerperarum*, Sagar, Sauvages. *Hysteritis*, Vogel, Cullen. *Metritis Puerperalis*, Boivin, Dugès. *Peritonitis Puerperalis*, Forster, J. Clarke, Hull. *Pièvre Puérpérale*, Fr. *Kindbetterinn-fieber*, Germ. *The low fever of child-bed*, John Clarke. *Child-bed fevers; severe child-bed fevers.*

CLASSIF. — III. CLASS, II. ORDER (Author in Preface).

106. DEFIN.—i. NOSOLOG. *Great frequency of the pulse, and pain, tenderness, and tumefaction of the abdomen occurring in the puerperal state; the pain often commencing in the pelvic region with rigours, the patient generally lying on her back, with the knees more or less elevated.*

107. ii. PATHOLOG.—*Fever occurring in the puerperal state; commencing, in some cases, in local disease, with rigours or chills; in other cases, from*

*infection of the frame and contamination of the fluids, with or without chills or rigours, and frequently with, but sometimes without, prominent local lesion of structure.*

108. When treating of FEVERS in an early part of this work, I took occasion to point out the several and very different forms or types which the febrile diseases of the puerperal state assume (see FEVER, § 44); and Dr. FERGUSON, in his classical work on "Puerperal Fever," has adduced the arrangement I then suggested, with others adopted by the more recent writers on puerperal diseases. It is evident, from what this able writer has stated, as well as from the best works which have been published on the subject since the middle of the last century, but still more from an extensive experience of puerperal diseases in different circumstances, seasons, and periods of their prevalence, that *puerperal fever* is not either a simple or an unvarying malady, and that, thus influenced, it assumes the most diverse types, forms, and complications, and often the most malignant and fatal character of any disease met with in European, or even in other countries. It is hence the more difficult to comprise within the succinct limits of a *definition* those characters which are applicable to all the states which puerperal fever may assume, without omitting what is really important, and at the same time embracing only such features as are essential to its actual and individual existence.

109. i. LITERARY NOTICES OF PUERPERAL FEVERS.—Previously to 1689 and 1733, when HAKE and BERGER wrote on the "Fever of Puerperal Females," no satisfactory account of puerperal fevers existed, although inflammation of the womb after child-birth had been noticed by FELIX PLATER and TULPIUS; and the diseases incidental to this period had been viewed as consequences of errors in diet and regimen, and of interruptions or suppressions of the secretions and discharges, by SENNERTUS, RIVERIUS, WILLIS, DE LA BOE, MAURICEAU, STROTHER, BOERHAAVE, and others. The earliest accounts of puerperal fever as a distinct malady appeared in inaugural dissertations, published at some of the continental universities. These were probably of some importance at the times of their appearance, as containing much of the experience and views of the professors in these institutions respecting this malady, the earliest of these having been printed at Leyden in 1689. In 1746, puerperal fever prevailed in Paris, chiefly at the Hôtel Dieu, where scarcely any recovered from it, the albuminous exudations found in the peritoneal cavity appearing like to coagulated milk on the surface of the intestines, with a copious effusion of whey or milk-like serum; and hence the effusion was viewed as a metastasis of the milk, although a slight attention to the history of these cases would have shown that the secretion of milk was not suppressed, or even interrupted. (FONTAINE, COL DE VILLARS, &c., in *Hist. de l'Acad. Roy. des Sciences*, 1746, p. 16.)

110. POUTEAU (*Mélanges de Chirurg.*, p. 180) mentioned the appearance of this malady in the Hôtel Dieu of Lyons in the spring of 1750, and its great fatality. He noticed sero-puriform effusion into the peritoneal cavity, thickening and contraction of the omentum, a relaxed and softened state of the uterus, and gaseous distention

of the intestines as the chief appearances on dissection, and was the first who regarded the disease as an epidemic erysipelatous inflammation of the peritoneum. Dr. HALL wrote an account of this fever in 1755; and SAUVAGES viewed it as inflammation of the uterus, occurring, 1st. In the puerperal state; 2d. Associated with typhoid fever; and, 3d. With suppression of the milk. STOECK has stated that puerperal fever broke out in the hospital of St. Mark, at Vienna, in 1770, and prevailed through that city during the two following years. It was characterized by pain in the hypogastric region and abdominal swelling, the uterus presenting marks of inflammation and gangrene, and the intestines being covered by false membrane. Dr. DENMAN was the first author, after Dr. HALL in Edinburgh, who attempted in this country to give an account of this malady; but he appears not to have examined the body after death from this disease, although he more correctly infers that the milky matter described by the French pathologists as existing in the peritoneum is a product of inflammation. Dr. MANNING wrote soon after (in 1771), and ascribed the disease to a putrid tendency in the humours; and HULME, LEAKE, and WHITE, who followed him in quick succession, while they viewed the disease as inflammatory, and as affecting chiefly the pelvic viscera and peritoneum, believed that it could not be ascribed to simple inflammation, but to the inflammatory associated with a putrescent disposition; and MILLAR subsequently adopted the same view.

111. Next to POUTEAU, KIRKLAND espoused the most rational doctrine of the nature of this malady, on which he wrote in 1774, and considered it as arising from, and consisting of, sundry pathological changes; from absorption of putrid or morbid matter from the uterus; from inflammation of the womb; from the retention and absorption of morbid secretions and excretions. He concludes that, while absorption of morbid matter and inflammation originating in the uterus will occasion puerperal fever, the abdominal lesions will also be consequent upon the fever when occurring primarily. While KIRKLAND thus wrote so creditably, this malady appeared in the Hôtel Dieu of Paris, and prevailed during 1774 and 1775, but presented nothing of additional importance to what had already been ascertained. During the middle and towards the close of the eighteenth century, the disease was observed by numerous physicians, many of them of great reputation, but little was added to the existing knowledge of its nature and treatment, the fatality caused by it in hospitals being often so great as to harass the feelings of those who were called upon to combat it. More or less detailed accounts of the pathology and treatment of the malady appeared during this period in the writings of STOLL, BANG, BURSERIUS, BUTTER, HECKER, DE LA ROCHE, DOUBLET, FRANK, REIL, and others referred to in the *Bibliography*, but there is nothing furnished by them deserving especial notice.

112. In 1787 WALSH wrote on the disease, and considered it as an infectious fever complicated with diffuse inflammation of the peritoneum. In 1787 and 1788 this malady was prevalent in the General Lying-in Hospital in London, and an account of the appearances ob-

served upon dissection was given by Dr. JOHN CLARKE in 1788 and 1793. In that manifestation of the disease the peritoneum presented the chief morbid changes, and these he has described with greater precision than any of his predecessors. He remarked that the uterus and ovaria sometimes partook of the inflammation of the peritoneum, but not more frequently nor more remarkably than other parts, and that the interior surface of the uterus was not inflamed. From this time, and guided by Dr. JOHN CLARKE's description of the changes after death, puerperal fever was viewed merely as *inflammation of the peritoneum in the puerperal state*; and this view was adopted by Dr. GORDON, of Aberdeen, by Dr. JOSEPH CLARKE, of Dublin, by Dr. HALL, Mr. HEY, Dr. CAMPBELL, Dr. MACKINTOSH, and by Dr. ARMSTRONG, with but slight modifications, or with no farther modification than the expressing of the same idea in somewhat different words; for in medical writings different words are too often substituted for different ideas. These writers bring down the literature of puerperal fever in this country to 1822; their works deserving notice chiefly as furnishing examples of a particular form or epidemic state of the disease, without any recognition of other still more important states observed by other authors, and insisted on by HAMILTON, BURNS, BOER, DOUGLAS, and others referred to in the sequel.

113. In 1823 I became consulting physician to Queen Charlotte's Lying-in Hospital, notorious at that time, and indeed for some years before and after that time, for the recurring appearances of this malady in the most malignant forms in its wards; and for several years subsequently to 1823 I had numerous occasions of there observing the several states of puerperal disease. Contemporaneously with my own researches, and still more recently, investigations of a similar nature were made both on the Continent and in this country; and the results proved that inflammation of the peritoneum, in some form or state, although one of the most constant, is not the only, and often not the earliest change; and that alterations of the uterus, its sinuses, veins, and appendages, are equally common. POUJEAU had stated, about a century ago, that the inflammation of the peritoneum and pelvic viscera, in puerperal fever, is of an erysipelatous kind; and the same opinion was subsequently maintained by HUNTER, GORDON, and others, and still more recently by numerous writers. Indeed, the erysipelatous or diffusive character of the inflammation, when once the disease has commenced, could neither be overlooked nor disputed; for this character is, as I have shown when describing the causes of puerperal maladies (§ 35-43, 130, *et seq.*), a necessary consequence of the operation of these causes, which, by their effects upon the states of organic nervous power and of the blood, preclude the formation, by the inflamed surface, of organizable or coagulable lymph, by aid of which the extension of the disease may be arrested.

114. It has been shown by KIRKLAND, and still more demonstratively by BANG, of Copenhagen—a pathologist whose clinical and necroscopic researches have not received their merited attention—that not only the uterus, but also the ovaries and the Fallopian tubes

were inflamed, softened, or contained purulent collections; and that the womb often presented various changes in its internal surface. Similar lesions were afterward described by JOHN CLARKE, SELLE, and OSIANDER, and more recently by numerous authors in Germany, France, and Great Britain. Inflammation of the uterine sinuses and veins was first distinctly described by BANG and J. CLARKE, and subsequently by DANCE, LUROTH, R. LEE, DUNPLAY, TONNELLÉ, CUSACK, INGLEBY, the author, and others, and shown to exist, in many cases of puerperal fever, by several of these writers. Dr. JOHN CLARKE, however, in 1793, attempted to prove that the low, or the most malignant form of this malady, is distinct from that which is attended by inflammation of the peritoneum, and of the uterus and its appendages; and although doubts have been expressed of the truth of this doctrine, still my experience has shown its accuracy, and has convinced me that a most rapidly fatal and most malignant form of puerperal fever is occasionally developed in lying-in hospitals which is certainly not characterized by uterine phlebitis, nor by purulent collections in the uterus or its appendages, nor even in some cases by peritonitis, the chief lesions often being merely a remarkable alteration of the blood, general lacerability of the tissues or loss of their vital cohesion soon after death, with a dirty, muddy, offensive, and sometimes scanty serous effusion into the serous cavities. It is true that the circumstances by which this form of the disease is developed are seldom observed, and still more rarely at the present day than formerly; but when once developed in these hospitals, under the circumstances in which I have observed it, not a single patient, within a week or fortnight from her delivery, will escape this pestilence, which may even be propagated abroad to puerperal females, if the proper precautions be not taken. When I became consulting physician in 1823 to Queen Charlotte's Lying-in Hospital, the wards were small, crowded, and without ventilation, a large number of females being confined in each ward; and, as might have been anticipated, *à priori*, a most pestilential form of puerperal fever was always recurring a few months after it was reopened, after each occasion of its having been shut up for the purposes of fumigation and purification. In the fatal cases—and at first all the cases were fatal—the appearances now stated were those chiefly observed, in some instances with more marked disease of the peritoneum, and a relaxed or uncontracted state of the uterus. Subsequently, when the representations of the medical officers procured enlargement and better ventilation of the wards, with a diminution of the number of beds in a ward, puerperal fever was of rarer occurrence, and assumed different types and forms, with the progress of these sanitary alterations, inflammatory appearances in the uterus and appendages, in the uterine sinuses and veins, and in the peritoneum, being then most frequently observed in fatal cases. As I believe that in the present and advancing state of medical science and of sanitary improvement, the circumstances which have produced the more malignant forms of puerperal fever, the local pestilence, which I had to treat many years ago, are not likely to exist and to

occasion a similar intensity of the disease, so I infer\* that the various stages of inflammation of the uterus, of its appendages, of the uterine veins, and of the peritoneum will constitute the chief lesions of puerperal fever; and that the type or character of the fever will entirely depend upon the state of inflammatory diathesis; upon the states of vital power and of the blood, accompanying the inflammation; and upon the absence or the presence of contamination of the circulating fluids by retained or absorbed morbid matters and excretions.

115. ii. ARRANGEMENT OF THE FORMS AND STATES OF PUERPERAL FEVER.—Numerous writers have described only one or other of the several forms or states of this fever, very probably from having seen only such form during a limited experience, and in peculiar circumstances, or from having described what they saw on a single occasion, or in a particular epidemic. That this has actually been the case is shown by the fact that these authors have not described the same form or variety, but each has adduced the variety he has described as the true and only form of the disease, and has been indignant at those who believed that any other state of the malady can exist excepting that which he has observed. Thus ARMSTRONG, HEY, MACKINTOSH, CAMPBELL, &c., who observed chiefly inflammatory forms of the disease, accompanied with a sthenic diathesis, could not tolerate the idea that any other state of the malady existed, and were most ireful at J. CLARKE, HAMILTON and others, who believed that a low, typhoid, or malignant form, very different from that which they described, sometimes broke out. Thus, from the days of STOLL and DOUGLASS to almost the present time, some writers have described only a single variety, and have believed it only to be the true malady. But, as will appear more fully hereafter, the symptoms, characteristic features, and still more the *post-mortem* appearances, display diverse features and extensive complications, according to the circumstances occasioning the disease and influencing its course.

116. Several writers, on the other hand, with stronger powers of observation, or with more extensive experience, have viewed puerperal fever as more or less varied in form and complicated in its nature, and not from a single position or aspect merely, as those just alluded to, but according as diverse circumstances, seasons, or epidemic influences have impressed on it different forms and complications. Thus JOHN CLARKE, having observed, 1st. Inflammation of the uterus and ovaria; 2d. Inflammation of the peritoneum; 3d. Inflammation of the uterus, Fallopian tubes, or of the peritoneum, connected with inflammatory fever; and, 4th. Low fever, connected with affection of the abdomen, which is sometimes epidemic, recognized three types or forms of puerperal fever: 1st. That consisting of local inflammation in the puerperal state; 2d. Primary inflammatory or synochal fever developing local inflammation; and, 3d. Typhoid fever with inflammation. Professor VIGAROUS next divided the disease into, *a.* The gastro-bilious; *b.* The putrid-bilious; *c.* The putrid, proceeding chiefly from season, &c.; *d.* The inflammatory, or associated with inflammation of the uterus, peritoneum, &c.; *e.* and the sporadic, arising from

mental causes, cold, &c. M. GARDIEN arranged the forms of puerperal fever into the following: 1st. The angiotonic, or strictly inflammatory; 2d. The adeno-meningic, or slow insidious fever; 3d. Meningo-gastric, with bilious derangement, yellow skin, &c; 4th. The adynamic; 5th. The ataxic or nervous; and, 6th. Fever with local phlegmasiæ.

117. Several continental writers on puerperal diseases have confounded those which belong more essentially to the puerperal state with those which may occur under every contingency, which are quite unconnected with this state, and are not more likely to affect puerperal females than other persons; and they have thus embarrassed the subject with complicated sub-divisions and compound terms. Thus BUSCH enumerates the following varieties in the local affection, occurring in the puerperal state: (*a*) Puerperal fever with inflammation within the abdomen; (*b*) With inflammation within the cranium; (*c*) With inflammation within the thorax; (*d*) With inflammation of the extremities; and he believes that the character of the fever may also be varied as follows: 1st. Gastric fever; 2d. Nervous fever; 3d. Typhus fever; and, 4th. Petechial fever. RIETZ, like BUSCH, has rendered what is often a very complicated subject still more complicated and involved by his mode of discussing it. He views puerperal fever as a disturbance of the economy in its attempts to bring the organism back to the unimpregnated state; and he contends, that any organ in the three cavities of the body may become inflamed during this disturbance. He considers the term "*Malacoplachnitis puerperalis*" as the best that can be applied to the malady, since not only may the peritoneum be attacked, but any other viscus also, the chief peculiarity being the marked tendency of the local lesion to terminate in large fluid effusion.

118. Dr. ROBERT LEE, who has directed his attention to the state of the uterine vessels in puerperal fever, has referred the symptoms to four varieties: 1st. To inflammation of the peritoneal covering of the uterus, and of the peritoneal sac; 2d. To inflammation of the uterine appendages, viz., the ovaria, Fallopian tubes, and broad ligaments; 3d. To inflammation and softening of the proper or muscular tissue of the uterus; and, 4th. To inflammation and supuration of the absorbents and veins of the uterus. It is manifest, however, that although cases will sometimes present one or other of these lesions, either singly or chiefly, much more frequently two or more of them will be associated in the same case; and therefore, instead of founding the varieties upon the individual lesions, it would be preferable to consider the local lesions as complications, or prominent changes occurring in the course of the malady.

119. The arrangement adopted by some other recent writers have been much more simple, and have possessed this recommendation, although it may have been carried too far. MARTENS acknowledges only the *inflammatory*, where one organ only is affected; the *nervous*, commencing with delirium; and the *putrid*, where the frame is more generally implicated. DOUGLASS has three forms, the *inflammatory*, the *gastro-bilious*, and the *epidemic*, or *contagious* or *ty-*

*phoid*. TONNELLÉ assigns only three varieties, the *inflammatory*, the *adynamic*, and the *atatic*. BLUNDELL adduces also three, the *sporadic*, the *mild epidemic*, and the *malignant epidemic*. This last physician believes that in this last form, where the epidemical disposition to peritonitis is strong, the diffusion of the inflammation is great and rapid, whence the difficulty of the cure; that in the milder epidemic the peritonitic disposition is weaker, and the inflammation of smaller extent; and that in the sporadic the epidemical constitution is wanting altogether, and the local affection is limited, and the treatment much more successful.

120. Dr. GOOCH, Madame BOIVIN, and M. DUCÉS have reduced the varieties to two: the *simple inflammatory form*, or metro-peritonitis, and the *typhoid*. In this last form, M. DUCÉS includes all cases of softening of the uterus and of suppuration of the veins; but he is certainly not accurate in his description of the symptoms characterizing it.

121. The author, in 1834, adopted an arrangement of the *forms or states* of puerperal fever (see article FEVER, § 44), which he had observed in practice, and which will be followed and illustrated in the sequel. In that arrangement the local affection or affections were viewed as often being accidents or contingencies in the progress of the fever—as complications supervening in its course; while inflammations of the uterus and its appendages, and of the peritoneum, were admitted to be sometimes primary diseases, of which the fever was symptomatic. Dr. MOORE, in his very excellent treatise, published in 1836, very justly remarks, that the varieties observed in the local lesions in puerperal fever, arising under the same circumstances, cannot be viewed as forms or varieties of the disease, which may be known by the symptoms, but should be considered rather as complications appearing in its course.

122. Dr. FERGUSON, in his very able work on this malady, assigns as the result of his extensive experience *four forms*: 1st. Puerperal fever characterized by abdominal pain; 2d. Fever with gastro-enteric irritation; 3d. Nervous form of fever; and, 4th. Complicated form of puerperal fever.

123. Dr. CHURCHILL, the most recent writer on puerperal fever, divides it, according to the predominant local affection, into *five varieties*, which he has placed in the order of frequency of occurrence: 1st. Peritonitis; 2d. Hysteritis; 3d. Inflammation of the uterine appendages; 4th. Uterine phlebitis; 5th. Inflammation of the absorbents. This arrangement is open to the following objections: (a) It takes for granted that the lesions of these individual parts are truly and always inflammatory—are, in truth, inflammation seated in one or other of these structures, and the fever the symptomatic constitutional expression of the inflammation of such structure—positions which cannot be supported by enlightened observations. (b) It leaves without any recognition or mention the type or nature of the fever as a consequence or effect of the exciting causes: it takes no account of the varying character of the constitutional disease, upon which, and upon it only, can rational and successful indications of cure be founded. (c) It takes for granted that these lesions are primary, although this is only

occasionally the case; and fails of viewing them, as they are presented in practice, in various circumstances, and in different endemic and epidemic states of prevalence. It is based upon a partial or piece-meal consideration of the malady, and instead of being founded on a comprehensive and mature digest of constitutional and local changes, it assumes that the nature of the constitutional affection, as well as of the local lesion, is always the same, the only difference being the part originally affected; and it remarkably fails in this distinction, inasmuch as the local changes are rarely limited to a single organ or tissue, but are generally extended to several, and even to many. When most strictly limited, the appropriation of symptoms, so as to mark the limitation, cannot be effected with either truth or accuracy.

124. The above divisions of the several forms of puerperal fever comprise those which appear most deserving of notice. The classification of these forms, adopted from the results of my experience, and published in 1834, and subsequently by Dr. FERGUSON in 1839, embrace, 1st. The *inflammatory states* of puerperal fever, or *inflammation*, (a) of the uterus, (b) of the ovaria and tubes, (c) of the peritoneum, (d) of any two or all of them. 2d. *Synchochoid puerperal fever*, complicated with inflammation—a, of the peritoneum, β, of the uterine veins, γ, of the uterus and appendages. 3d. *Adynamic or malignant puerperal fever*—a, simple; b, complicated with predominant alteration; α, of the blood; β, of the fluids and peritoneum; γ, of the fluids, serous surfaces, and soft solids generally; δ, of the uterus, or of the uterus and appendages; ε, of the internal surface of the uterine vessels, substance of the uterus, &c.—(a) The *first form* comprises the *primary or idiopathic inflammations*, most liable to occur in the puerperal state, and which, commencing in either of the organs or structures here specified, are attended by symptomatic fever, characterized according to the diathesis, strength, and circumstances of the patient, and are limited, or more or less extended or associated, according to these and other influences and causes.—(b) The *second form* embraces those cases of frequent occurrence, especially in lying-in hospitals, in which it is difficult to determine whether the fever or the local affection is primary, or in which the local alterations rapidly follow the constitutional or febrile affection. In this form of the disease the symptoms are much more asthenically inflammatory than in the first, more insidious at the commencement, and often referable to a local contamination or infection. It may prevail in lying-in hospitals, on certain occasions which admit not of precise description, and may be propagated by contagion. It is not infrequently connected with the prevalence of erysipelas. I have seen it in the wards of hospitals which have not been over-crowded or apparently ill-ventilated.—(c) The *third form* is the most malignant, and in its most intense and pestilential states is seen chiefly in lying-in hospitals, or wards, when over-crowded and ill-ventilated. The whole frame appears infected from the commencement, and whatever local affections or lesions may exist are developed in the progress of the malady, such lesions merely presenting more prominent forms than those observed in other parts of the body. This

form of puerperal fever is caused by the local or endemic infection of the ward—by respiring an infected atmosphere; the infection originating as stated above. The disease produced by it may terminate rapidly in death, without any tissue or viscus having presented a more prominent lesion than the rest of the body. The blood, however, always is more or less altered, and the tissues generally are very deficient in vital cohesion immediately after death. When this form of the malady is less rapidly fatal, one or more of the complications, or rather of the more prominent alterations enumerated above, are generally observed.

125. Between the more primary inflammations, appearing sporadically, and constituting the *inflammatory form* of puerperal fever, and the *malignant form* now mentioned, that form which I have named the *synchooid* holds an intermediate place, passing insensibly into either of the other forms with the intensity of the exciting causes and the amount of predisposition. This *synchooid* or *intermediate form* may arise not only from a less concentration of the causes; from a less impure or contaminated air; from a less concentrated or intense effluvia; but also from an impure or infected state of the bed or bed-clothes, or from the infected hands of the accoucheur, causing a local infection during examination; or from other circumstances either already or about to be noticed; but according to the nature of the causes, their concentration, the state of the patient and the predisposition, so will it approach either the inflammatory form on the one hand or the malignant on the other; and so will it occur sporadically, or even extend by infection.

126. Another circumstance deserving a brief notice is the fact, which has been presented to me on several occasions, that, although the cases which occurred when ventilation was most deficient were generally of the third or most malignant form I have mentioned, yet occasionally a less malignant case, or one more properly belonging to the second form, presented itself, and was to be ascribed to the greater constitutional powers of the patient. But during this state of ventilation and infection not one escaped the disease who was confined in the hospital. Subsequently, when ventilation was improved, and when a fever ward was provided outside the institution, the cases presented generally the second form, and very few of the most malignant or third form were then seen.

127. Besides these three forms of puerperal fever, with their complications or more prominent lesions, another may be adduced, namely, infectious, or *truc typhus fever* occurring in the puerperal state; and of which I have seen a few instances. The infection may have been received before or after delivery; but typhus fever appearing in this state should no more be viewed as a form of puerperal fever than small-pox, or any other of the exanthematous fevers ought to be so considered, when attacking a woman in child-bed. I shall, therefore, notice it no further than the diagnosis may require.

128. In the several works which have appeared upon puerperal fever, the *epidemic* and the *sporadic* occurrences of its several forms have been mentioned in a very loose manner. I have no doubt of any of the forms of the mal-

ady appearing sporadically, more especially the first and second forms which I have assigned, when circumstances combine to develop them; nor can I deny that any of these forms, more particularly the second and third, may become so prevalent, owing to a combination of causes, as to deserve the epithet epidemic. But most of the instances in which puerperal fever has become so prevalent as to be so called have occurred in lying-in wards; and the disease has been limited to them, unless on some occasions when the infection has been carried abroad from them. The term epidemic is, therefore, not strictly applicable, the malady being truly *endemic* as respects such institutions as thus occasion it, the character, the type, intensity, and other features of the malady depending much upon the *endemic sources*—upon the concentration of the infectious effluvia and other causes generated in these institutions and wards. It is not improbable, however, that certain atmospheric constitutions, depending upon the states of terrestrial and atmospheric electricity, and of humidity and temperature, and other circumstances affecting the prevalence of febrile maladies, may so affect also the form and prevalence of puerperal fever as to render it not only endemic in lying-in hospitals, but also epidemic, or approaching to this state, in various places in which it may break out. For, as I stated above (§ 36, 44, 138), causes similar to, or almost identical with, those which generate it in the lying-in wards, actually exist in various houses and localities, in such forms and degrees of concentration as to give rise to sporadic cases, which, when circumstances combine to favour their spread, may propagate the malady.

129. It will be asked, what are these causes which thus exist locally or endemically? 1st. Beds and blankets contaminated by prolonged use, without any attempts at purification (§ 44); 2d. Privies containing immense accumulations of faecal matters, often rising as high as the boards, emitting contaminating vapours, particularly when frequented or disturbed, and sometimes occasioning, as I have remarked in several instances, asthenic or irritative and spreading inflammation of the vulva, vagina, and cervix uteri of married females, and even also of the rectum. I am convinced that the domestic causes of disease, and even of the most malignant maladies, which I have described in the article PESTILENCES, PROTECTION FROM (§ 10–23), and of which I have even assigned proofs (§ 14) at that place, are mainly concerned in producing the more serious forms of puerperal disease, the malignancy of the attack depending chiefly upon the concentration or intensity of the cause.

130. iii. CAUSES.—The *causes of puerperal diseases* have been stated above, with reference both to the peculiar condition of the puerperal female, or the predisposition thereby acquired (§ 6, *et seq.*), and to the more efficient and immediate agents and influences (§ 35, *et seq.*, 129). These are disposing and exciting causes, which with their several concomitants, and especially when present in concentrated or intense forms, commonly occasion puerperal fevers—produce it sporadically and favour its spread. From the days of HIPPOCRATES down to the close of the last century, the suppression of the lochia

or of the milk was viewed as the chief cause of puerperal fevers; and certainly there can be no doubt that the suppression of these will often be followed by very serious disease, particularly of a febrile kind. But in most instances the suppression is merely one of the effects of antecedent causes; and it may not—indeed, most frequently it does not—take place in the most malignant states of the disease.

131. *A.* The *predisposing causes* of puerperal diseases have been already enumerated, and the influence of mental emotions has been noticed. The depression caused by *fear* of the disease, especially in lying-in charities, when the death of a patient is known, has a remarkable effect in favouring the extension of the disaster, and the *depressing feelings* entertained by unmarried puerperal females exert a similar influence. *Large losses of blood*, by uterine hemorrhage or otherwise, have a manifest influence, not only in predisposing to, but also in aggravating the danger of this disease, more especially in lying-in hospitals and wards. Several instances demonstrating the truth of this statement have been observed in the course of my experience. Hemorrhage appears to increase the predisposition, both by augmenting vital depression and shock, and by favouring the absorption of morbid secretions and excretions, and the passage of contaminating effluvia into the circulation.

132. Hydrometric and thermometric states of the *atmosphere* also favour the occurrence of puerperal fever, both by depressing nervous power and by concentrating animal exhalations. Cold and humid states of the air frequently prevent due ventilation of wards and apartments, and the requisite dilution of the contaminated atmosphere; and all methods of warming lying-in apartments which do not promote due ventilation, or currents of fresh air, tend remarkably to generate a pestilential effluvia in lying-in wards or hospitals. *Humidity* at all seasons, but more especially during winter and spring, favours the generation and propagation of this and its allied diseases, as remarked by writers of all ages, more especially of erysipelas, fever, dysentery, and rheumatism.

133. Some difference of opinion has existed respecting the seasons and states of the weather favouring the development of puerperal fever, especially in lying-in wards. My experience convinces me that *cold* is influential chiefly by preventing that amount of ventilation which is requisite when several women are in child-bed in the same apartment. According to my own observations, during a period of thirty years, the disease has been most prevalent during the last three months and the first four of the year. M. DUGÉS's observations, which are limited to 1819 and 1820 merely, show an order of frequency as follows: November, February, January, October, December, September, May, March, April, August, July, June. M. DE LA ROCHE, of Geneva, exhibits the following order of prevalence: January, March, November, December, April, October, September, February, July, August, May, June. As respects the influence of humidity there is greater uncertainty. But I believe that a moist state of the air, especially when conjoined with a low temperature, is most injurious, especially as respects lying-in wards; and in this opinion I

am supported by CHAUSSIER, DUGÉS, CLEIT, and others, while M. DE LA ROCHE considers that a dry state of the air is most favourable to the prevalence of the malady. Humid states of the atmosphere, conjoined with warmth and stillness, are certainly not infrequently productive of sporadic cases arising from the local sources of contamination and infection already pointed out (§ 36, *et seq.*); and from these cases either contagion or infection may extend, when the media are suitable to the transmission, especially by the midwife or nurse.

134. But neither temperature nor grades of humidity, nor both conjoined, always account for the prevalence or absence of this distemper. There seems to be a disposition to the prevalence of it at some periods and not at others, independently of the conditions now remarked upon. The states of the electricities, in as far as they affect the human body, may be the cause of this predisposition, or emanations from the soil, of a nature quite incognizable to our senses and means of detection, may favour its development and diffusion. But the epidemic occurrence of the malady seems allied to the prevalence of low, or adynamic, or eruptive fevers, more especially of typhus and erysipelas; and when puerperal fever is found to prevail in lying-in hospitals, independently of crowding or want of due ventilation, it generally partakes of the nature of the prevailing epidemic, or of the general epidemic constitution.

135. Neglected states of the bowels, constipation, or diarrhœa; improper or insufficient food; addiction to the use of spirituous liquors or cordials, and living in low, ill-drained, and ill-ventilated houses, also predispose to puerperal fevers. It is difficult to determine the influence of first or subsequent labours, or of the kind of labour. But very quick labours have been viewed as favouring the occurrence of puerperal disease in those confined for the first time; and prolonged or difficult labours in subsequent confinements. Premature labour seems to dispose to puerperal fever; but it may be mentioned that, when the patient is infected by the disease previously to delivery, or to the full period of gestation, premature labour will be thereby induced. Of this I saw two instances in consultation with medical friends in the winter of 1827 and 1828.

136. Other circumstances often concur with the foregoing in predisposing to puerperal fevers, more especially an age approaching to or above forty years; females who have suffered previous abortions, and who are vitally or mentally depressed or exhausted; severe, prolonged, or instrumental labours; those who have been subject to diarrhœa, hemorrhoids, or leucorrhœa; and those who are cachectic, or have been ill-fed, or kept *too low* during their confinement. Indeed, insufficient nourishment, or *inanition*, in the puerperal state, is a more frequent predisposing cause than usually believed. These require no remark, especially when they are concomitants of the foregoing causes, and with other states of predisposition noticed above. (*See* § 6, 10, *et seq.*)

137. *B.* The *exciting causes* are chiefly those which tend to contaminate the atmosphere of the lying-in apartment, or which may occasion a local infection.—(a) The *sources* of contamination have been described above (§ 35, *et seq.*,

128, 129); and although their nature and effects must have been long ago recognised, their removal and prevention have hitherto received very slight attention. But these are not the only sources. Many houses retain within their own walls sufficient causes of contamination and of local infection, as just stated, and as fully demonstrated under the head *PESTILENCES, protection from* (§ 10-23). These causes are often productive of dysentery and of asthenic inflammation of the vagina and uterus, and they may be inferred not to be less innocuous to females on the eve of delivery, the foul air evolved from these sources infecting the female organs, and thus producing sporadically either some one of the forms of puerperal fever, or uterine diseases incidental to the puerperal state. That these maladies have been thus produced in several instances I have had sufficient evidence to prove; and that the more febrile or severe may be propagated to other females in this state, when circumstances combine to favour the propagation, I firmly believe. Besides these sources of *extrinsic* contamination, and the effluvia disengaged from foul beds (see § 44), there are other influential causes which should not be overlooked, namely, direct and mediate contagion or infection, and the *intrinsic* contamination caused by morbid matters imbibed, and carried into the circulation from the uterus and vagina.

[The epidemic puerperal fever which proved so fatal among the lying-in patients of the New York Alms-house at Bellevue in 1840, could be distinctly traced to a vitiated state of the atmosphere, both general and local. For twelve or fifteen months preceding, there had been an unusual tendency to epidemic disease, generally of a typhoid character. An incurable diarrhœa, followed by mortification of either extremity of the alimentary, often with the loss of eyes, defied the efforts of medicine. Mortification often succeeded blood-letting. Ophthalmia, when treated in the usual antiphlogistic manner, was followed by rapid ulceration of the cornea. Scarlatina was very malignant and fatal. In short, there was a universal typhoid tendency in all diseases, requiring a tonic and supporting course of treatment.]

138. Not the least important of the exciting causes of sporadic cases, which, however, in circumstances favouring infection, may become more or less prevalent, is confinement in a low, close apartment, near where the exhalations from privies, cess-pools, or drains find an outlet and contaminate the air. Apartments near the ground floors of houses which are provided with privies and cess-pools that have no communication with drains and sewers—and most houses are thus most injuriously constructed—are liable to have the air in them contaminated at all seasons from these sources; but more especially in winter, when they are kept more closely shut, and when the exhalations arise not much less abundantly, and penetrate wherever hydrogenous exhalations may possibly pass.

139. The unguarded use of improper beverages, as beer, ale, wine, spirits, &c.; all sudden mental emotions, or shocks, frights, chagrin, anxieties, &c., and premature excesses of any kind, may concur to induce an attack of certain forms of the disease, especially of the more inflammatory. Coagula in the womb, or

retained in the vagina; portions of the placenta left adhering to the uterus, and death of the fœtus in utero, may severally cause uterine phlebitis, or other forms of this disease, especially if the labour has been tedious, or has required the use of instruments.

140. (*b*) *The infectious nature* of puerperal fever has been denied by some, proved and believed in by many, and imperfectly elucidated, or stated without precision or due limitation by most recent writers on the disease. Infection, or even contagion, is undoubted—unless by the inexperienced and the skeptical—in certain circumstances and forms of the malady. MM. TONNELLÉ and DUGÉS, however, do not believe in the contagious nature of puerperal fever, and adduce their experience at the Maternité in Paris in support of their opinion. During the latter part of 1818 and spring of 1819, the disease was extremely prevalent in Paris, where I was then residing, and had an opportunity of seeing some of the cases which were so numerous in that institution, where alone about three hundred women died of it in these two years. It was prevalent at that time not only in lying-in wards, but also throughout Paris and its environs. These physicians state that it did not extend itself to the bed nearest that in which a patient was affected by it; and they assert that women newly delivered there had each a separate apartment, and yet were attacked. These are the chief facts in proof of their opinion, but they prove nothing beyond what has often been demonstrated (see § 143, *et seq.*), viz., that the malady is often propagated by the mediate contact of the hands of the midwife, and by the effluvia imbibed and conveyed by the clothes. They, however, admit, what was generally observed, both there and in other institutions, that when the fever was prevalent it generally attacked several in the same ward, and was sometimes confined entirely to one ward, a fact sufficiently demonstrative of at least an infectious or contaminated state of the air or of the bedding in that ward.\*

(\* Dr. VACHE, of New York, has given a very interesting account of the prevalence of epidemic puerperal fever at the New York Alms-house in 1840. The disease made its appearance in the Alms-house on the 12th of June, 1840, and was quickly followed by two more cases, apparently so malignant that it was immediately determined to vacate the room, with a view to its purification. The inmates were accordingly removed, and the apartment was whitewashed, ventilated, and scrubbed; the bedsteads were cleansed, new beds and bedding introduced, and at the expiration of about a week it was considered sufficiently disinfected to return to it in safety. But the disease immediately reappeared, equally as violent and irremediable as before, and it was concluded most judicious to abandon the building. Another was therefore prepared at some distance from the Alms-house, and appropriated as a nursery, after being put in the most perfect order; the bedsteads were cleansed and painted; new beds and bedding were furnished; the physician and nurse were changed; the pregnant women were directed to cleanse their persons by bathing; new clothes and shoes were given to them immediately previous to transferring them to their new habitation, and all intercourse arrested with the inmates of the surrounding premises. Notwithstanding these precautions, the first woman confined, and subsequently four others in succession, out of five labours, were attacked with the disease, and in every case it was fatal. The lying-in apartments at Bellevue were then abandoned, and others procured at Blackwell's Island. The same precautions were observed, and for a time the change of air, free ventilation, and a more generous diet seemed to have accomplished the object; several were delivered, convalesced, recovered, and were discharged without an untoward symptom; but the disease soon broke out with redoubled fury, attacking almost every woman confined, and setting at defiance every effort for their recovery. The disease in each locality was almost uniformly fatal. The treatment was diversified, consisting a

141. A circumstance worth noticing is mentioned by M. DUGÈS, which is no mean proof of the influence of the infected air of the hospital upon the lower animals. During 1819 several cats, frequenting the wards of the Maternité during the prevalence of fever, were attacked by painful distention of the abdomen, and tumefaction of the parts of generation. The most of them died in four or five days; and the dissection of them was made, in the presence of Professor CHAUSSIER, by M. DUGÈS, who found in the peritoneal and pleural cavities a large quantity of a whitish serum mixed with albuminous flocculi, and a thin whitish coating covering the abdominal and thoracic viscera. A similar instance of the cat of the hospital becoming infected occurred in the hospital to which I was consulting physician during the prevalence of the fever in it.

142. In 1824, I was requested by a practitioner in the Edgeware Road to see a patient with him in this disease. She was the sixth case which he had had in the course of a few days. She was moribund when I saw her. I learned from him that each case of midwifery which he had attended from the first of these six cases was attacked in succession and had died; that he had called the most eminent accoucheurs to see these cases; that they had prescribed large bleedings; and that the present case had been also largely bled, as was then the general practice, the injurious effects of which were making themselves apparent. I insisted that contagion had caused these cases, advised measures to be taken against his being the medium of its transmission, and no other cases occurred to him for a considerable time.

143. Dr. CAMPBELL wrote on this disease in 1822, from a short experience; and, because he saw no reason to satisfy himself of the propagation of it by contagion, contended, in opposition to the no mean authority and more extensive experience of HAMILTON and GORDON, that the disease was neither infectious nor contagious, although he has adduced no conclusive evidence that some, at least, of the numerous cases which occurred in 1822 did not arise from contagion. It must be admitted that the sources of sporadic contamination which I have described above (§ 137, 138), are so abundant in Edinburgh, where Dr. CAMPBELL practiced, that the difficulty of discriminating between the influence of these and of contagion is thereby much increased. With a candour which always characterizes the truly scientific inquirer, this physician states that subsequent experience has shown him his error (*Lond. Med. Gaz.*, Dec., 1831), and, much to his credit, he adduces the following facts: After examining the body of a female who died of the disease after an abortion, and carrying some of the diseased parts to the class-room, he attended the delivery of a woman the same evening without having changed his clothes: she died. Next morning he went in the same clothes to assist a difficult case, the subject of which also died of the disease; and of others who were seized, within a few days, three shared the same fate. In June, 1823, he assisted at the dissection of

a case, where, from want of accommodation, he was unable to wash his hands with due care. He was soon after called to two patients requiring assistance, and went without farther ablution, and without changing his clothes, and both these were seized with the disease and died.

144. Dr. GORDON states, that the malady attacked only those women who were attended by a physician or nurse who had previously attended those affected with it. He remarks, that he had abundant proofs that any person who had been with a patient in puerperal fever became charged with an atmosphere of contagion which infected every pregnant or puerperal woman who came within its sphere. Dr. HAMILTON affirms that this fever is produced by an infection *sui generis*, and that he is quite positive that this infection is of so virulent a nature that it may be conveyed by a third person. Dr. GOOCH records that a surgeon, after opening the body of a woman who died of this disease, continued to wear the same clothes, and delivered a lady a few days afterward, who was attacked by a similar malady and died. Two more of his patients were seized in rapid succession, and also died. He then suspected the transmission of the infection by his clothes, changed them, and met with no more cases of the distemper. A washerwoman and nurse washed the linen of a female who had died of puerperal fever. The next lying-in patient she nursed died of this disease, and so did a third; when the circumstance having become known, she was no longer employed. At Sunderland, forty out of fifty of these cases occurred in the practice of one surgeon and his assistant. Many other proofs of infection have been adduced by Drs. LEE, MOORE, WALLER, ROBERTSON, and by many recent writers. The last-named writer, in a most instructive communication (*Lond. Med. Gaz.*, vol. ix., p. 503), states, that a midwife in extensive practice among the out-patients of a lying-in charity, within one month delivered thirty cases living in an extensive suburb of Manchester, and of this number sixteen were attacked with puerperal fever, and they all died; and that, of about three hundred and eighty delivered at this time by the midwives of this charity, none had the disease except the patients delivered by this midwife. Other conclusive facts are adduced of contagion by this writer.

[Numerous facts of a similar kind have fallen under our observation during a practice of twenty-two years, mostly in this city; but we conceive it unnecessary to go into detail to prove the contagious nature of this disease, as there are few, if any, American practitioners who do not fully believe in this doctrine. In three instances we have known the disease to follow up the accoucheur so closely that he has found it necessary to relinquish practice for a season, notwithstanding all the precautions he could use to avoid extending the disease through the medium of his clothes, &c. There is something truly remarkable in the extreme tenacity of this animal poison, and the minuteness of dose necessary to infect the lying-in female, as well as the certainty of infection upon exposure to the smallest particle of the infectious matter.]

145. These facts sufficiently show the contagious nature of this disease; that this fever may be propagated both by the hands, and by

general bleeding, cups, leeches, blisters, and fomentations to the abdomen, Dover's powder, camphor, turpentine, calomel, and opium, mercurial purgatives, Peruvian bark, stimulants, &c.]

the clothes, or by either, of a third person, that third person being generally the midwife or nurse. But not only is it thus contagious—the tangible communication often taking place during an examination *per vaginam*—but it is also infectious through the medium of the bedclothes or bedding, or the body-clothes of a patient, or of a midwife or nurse, or the contaminated air of a lying-in ward. I have had several occasions of observing that a lying-in hospital, or ward, for some time after having been opened or purified, will remain free from puerperal disease; but that, if too many patients be admitted, or if, owing to the season, weather, temperature, and humidity, the wards are too closely shut, the emanations from the discharges, &c., will soon contaminate the air, and infect the more recently-delivered women, the effluvia from those first attacked increasing the infectious state of the air, which is confined for a time to the wards where the emanations were first accumulated, but which soon becomes diffused through all the wards and apartments.

146. It has been very justly remarked by Dr. HOLMES, of Boston, United States, that, "suppose a few writers of authority can be found to profess a disbelief in contagion—and they are very few compared with those who think differently—is it quite clear that they formed their opinions on a view of all the facts; or is it apparent that they relied mostly on their own solitary experience?" Dr. DEWEES, in the last edition of his treatise on the diseases of females, has expressly said, "In this country, under no circumstance in which puerperal fever has hitherto appeared, does it afford the slightest ground for the belief that it is contagious." The evidence already furnished may be viewed as quite decisive of the infectious and contagious nature of the disease in Europe; but Dr. DEWEES is incorrect as to his statement of the matter as respects the United States; for, as Dr. HOLMES has remarked, Dr. FRANCIS states that the disease was, in some instances, supposed to be conveyed by the accoucheurs themselves; and Dr. PIERSON, of Salem, United States, admits this to have occurred to himself in several consecutive cases. Dr. CONNIE, although not previously a believer in the contagious nature of the malady, "has, nevertheless, become convinced by the facts that have fallen under his notice, that the puerperal fever now prevailing is capable of being conveyed by contagion." (*Trans. of Coll. of Phys. of Philadelphia*, July, 1842.) Dr. WARRINGTON stated at the same meeting of the college, that, after assisting at an autopsy of puerperal peritonitis, he was called upon to deliver three women in rapid succession. "All these women were attacked with different forms of what is commonly called puerperal fever." At this meeting, also, Dr. WEST stated that seven females delivered by Dr. JACKSON in rapid succession were all attacked with puerperal fever, and five of them died. These were the only cases which occurred in that district; for the women became alarmed at the existence of what Dr. DEWEES and a few with him have denied, and sent for other assistance. "And here I may mention that this very Dr. S. JACKSON is one of Dr. DEWEES's authorities against contagion!"

147. A physician in Boston, United States, had the following consecutive cases: on the

24th March, 9th, 10th, 11th, 27th, 28th April, and 8th May, seven in all, of which five died. He then left town. Another physician writes to Dr. HOLMES as follows: "The first case was in February (1830), during a very cold time. She was confined the 4th and died the 12th. Between the 10th and 28th of this month I attended six women in labour, all of whom did well except the last, as also two who were confined March 1st and 5th. Mrs. E., confined February 28th, sickened and died March 8th. The next day, the 9th, I inspected the body, and the night after attended a lady, Mrs. G., who sickened and died the 16th. The 10th I attended another, Mrs. B., who sickened, but recovered. March 16th, I went from Mrs. B.'s room to attend a Mrs. H., who sickened and died 21st. The 17th I inspected Mrs. G. On the 19th I went directly from Mrs. H.'s room to attend another lady, Mrs. G., who also sickened and died 22d. While Mrs. B. was sick on the 15th, I went directly from her room, a few rods, and attended another woman who was not sick. Up to the 20th of the month I wore the same clothes. I now refused to attend any labour; and did not till April 21st, when, having thoroughly cleansed myself, I resumed my practice, and had no more puerperal fever. The cases were not confined to a narrow space. The two nearest were half a mile from each other, and half that distance from my residence. The others were from two to three miles apart. There were no other cases in their immediate vicinity." (P. 517.) In another communication, the writer considered that he carried the contagion to five cases; and both he and the preceding correspondent state that the disease infected the young and the more aged—the strong and the weak; and without being influenced by the labour or other circumstance.

148. Dr. RAMSBOTHAM remarks, that he has known the disease to spread through a particular district, or to be confined to the practice of a particular person, almost every patient being attacked by it, while other practitioners had not a single case; and he views the distemper as being capable of conveyance in not only common modes, but through the dress of the attendants on the patient. (*Lond. Medical Gaz.*, 2d May, 1835.) Dr. BLUNDELL says, that some practitioners have lost ten, twelve, or a greater number of patients in scarcely broken succession; "that this fever may occur spontaneously, he admits; that its infectious nature may be plausibly disputed, he does not deny; but he would considerably add, that he had rather "that those he esteemed the most should be delivered, unaided, in a stable, by the manger-side, than that they should receive the best help in the fairest apartment, but exposed to the vapours of this pitiless disease. Gossiping friends, wet-nurses, monthly nurses, the practitioner himself, are the channels by which the infection is chiefly conveyed." (*Lect. on Midwifery*, p. 395.) My friend, Dr. KING, of Eltham, mentioned at a meeting of the Medical and Chirurgical Society (*Lancet*, 2d May, 1840), that some years since a surgeon at Woolwich lost sixteen patients from puerperal fever in the same year. He was compelled to give up practice for one or two years, his business being divided among the neighbouring practitioners. No case of the disease had occurred in the practice of these

practitioners, or occurred afterward. Mr. DAVIES states, that in the autumn of 1822 he met with twelve cases, while his medical friends in the neighbourhood did not meet with any, or at least with very few. He could attribute this to no other cause than his having been present at the examination of two cases, and his having conveyed the infection to his patients, notwithstanding every precaution. In December, 1830, a midwife who had attended two fatal cases of puerperal fever at the British Lying-in Hospital, examined a patient who had just been admitted to ascertain if labour had commenced. This patient remained two days; but labour not coming on, she returned home, when she was suddenly delivered before she could return to the hospital. On the third day she was seized with the fever, and died in thirty-six hours. A young surgeon, shortly after examining the body of a sporadic case that had died, delivered three women, who all died of puerperal fever. Mr. INGLEBY states, that two gentlemen, after the post-mortem examination of a case of this disease, went in the same dress, each respectively, to a case of midwifery. The one case was attacked in thirty hours afterward, the other in three days. One of the same surgeons attended, in the same clothes, another female, and she was attacked on the evening of the fifth day, and afterward died. These cases belonged to a series of seven, the first of which was believed to have originated in a case of erysipelas. Mr. INGLEBY also adduces another series of seven cases which occurred to a practitioner in 1836, the first of which was also attributed to his having opened erysipelatos abscesses shortly before.

149. Dr. RIGBY remarks, that the discharges from a patient in puerperal fever are highly contagious; that the puerperal abscesses are also contagious, and may be communicated to healthy lying-in women by using the same sponge, as proved repeatedly in the Vienna Hospital; and that the women engaged in washing the bed-linen of the General Lying-in Hospital have been attacked with abscesses in the hands and diffuse inflammation of the cellular tissue. Dr. RAMSBOTHAM, in a letter to me, mentions a series of seven cases, two of which he saw, which occurred successively to a surgeon in this city; and he, moreover, notices the connexion of erysipelas with certain of these cases; but to this I shall revert in the sequel. Now, after the evidence I have adduced—and I could have quadrupled the amount—is it not criminal for any medical man to go from a case of this disease, or even from a case of erysipelas, to a female in the parturient or puerperal state, without using the strictest precautions? I may conclude this part of my subject by stating that the fact of the contagious nature of this malady is completely set at rest by the above evidence, especially when it is undisputed that within the walls of lying-in hospitals a miasm is often generated as palpable to the senses, and even sometimes much more so, than the fumigations used to destroy it, so tenacious as often to withstand the common measures of purification, and, when generated, more deadly than the plague, if not arrested at its commencement by the most prompt and efficient means. I may farther add, that lying-in hospitals, or even lying-in wards, ought not to be

allowed to exist, for the reasons rendered apparent by what I have adduced, and because the aid they afford may be more beneficially furnished in other ways; and that boards of health, if such existed, or without them, the medical institutions of a country, should have the power of coercing, or of inflicting some kind of punishment on those who recklessly go from cases of puerperal fevers to parturient or puerperal females, without using due precaution; and who, having been shown the risk, criminally encounter it, and convey pestilence and death to the persons they are employed to aid in the most interesting and suffering period of female existence.

150. The contagious nature of puerperal fever has been denied by HULME, LEAKE, HULL, BEAUDELOCQUE, TONNELLÉ, DUGÉS, DEWEES, and others; but GORDON, J. CLARKE, DENMAN, BURNS, HAMILTON, HAIGHTON, GOOCH, BLUNDELL, RAMSBOTHAM, LOCOCK, DOUGLAS, LEE, INGLEBY, ALISON, RIGBY, WATSON, CHANNING, and others have professed their belief in, or adduced proofs of, the existence of this property, as respects this, the most frightful of any of our domestic pestilences; and if any would prefer the weight of authority to the overwhelming evidence now adduced, the names I have enumerated must satisfy him—at least they are quite, nay, more than sufficient to warrant him in acting with caution, and to render him criminal in the eyes of the considerate part of the community if he should ever be the medium of transmitting contagion and death to those who confide not only in his science, but also in his humanity, and in the incalculable value attached by him to human life. Dr. HOLMES has forcibly and eloquently brought this much-neglected subject before the profession; and he thus concludes: "It is as a lesson, rather than as a reproach, that I call up the memory of those irreparable errors and wrongs. No tongue can tell the heart-breaking calamity they have caused; they have closed the eyes just opened upon a new world of love and happiness; they have cast the helplessness of infancy into the stranger's arms, or bequeathed it with less cruelty the death of its dying parent. There is no tone deep enough for regret, and no voice loud enough for warning. The woman about to become a mother, or with her new-born infant upon her bosom, should be the object of trembling care and sympathy wherever she bears her tender burden or stretches her aching limbs. The very outcast of the streets has pity upon her sister in degradation when the seal of promised maternity is impressed upon her. The remorseless vengeance of the law is arrested in its fall at a word which reveals this transient claim for mercy. The solemn prayer of the Liturgy singles out her sorrows from the multiplied trials of life, to plead for her in the hour of peril. God forbid that any member of the profession to whom she trusts her life, doubly precious at that eventful period, should hazard it negligently, unadvisedly, or selfishly!"

151. *C. What connexion is there between puerperal fevers and erysipelas?*—The connexion apparently existing between these diseases has been hinted at above; but it is more remarkable at some seasons and occasions than at others. It was first observed and insisted upon by POUTEAU in 1750, who considered the puer-

peral fever as it then prevailed in Paris as an epidemic erysipelas of the peritoneum. Drs. HOME and YOUNG, of Edinburgh, and Dr. LOWNER, of London, not long afterward, also maintained this opinion. Dr. ABERCROMBIE, as Dr. MOORE has remarked, adopted a similar view, and founded his opinion principally on the circumstance of both diseases giving rise to serous effusion. In the various discussions this subject has given rise to, it has been contended by Dr. WHITING, Dr. WALLER, and others, that the identity of both these maladies is shown by the similarity of symptoms, and by the ill success of remedies; they asserting that, like erysipelas, puerperal fever cannot be arrested, and that it is contagious. This last property has been shown to exist, and cannot now reasonably be doubted. But that puerperal fever may be arrested I have proved on numerous occasions; and I shall have occasion to describe the means by which its arrest may be accomplished. Phlebitis of the capillary veins not infrequently complicates erysipelas, and uterine phlebitis is a frequent complication of the second or more intermediate grades or states of puerperal fever. These phenomena evince a certain amount of alliance, but not identity. GORDON, HEY, ARMSTRONG, and others contend for similarity, if not for identity. Dr. LEE states that in 1829, when the fever broke out in the British Lying-in Hospital, three children died of erysipelas, and on examination after death, the peritoneum in these infants was found extensively inflamed, and covered with a copious sero-purulent effusion. Three other cases are related as having occurred under similar circumstances; but it is admitted that cases of infantile erysipelas repeatedly occurred when there were no cases of puerperal fever in the hospital. I find it remarked, in my notes of cases of this disease observed by me in Queen Charlotte's Lying-in Hospital, that the relation subsisting between puerperal fevers, whether of an inflammatory, or of a malignant, or of an intermediate type, and erysipelas, especially of an epidemic form, has been evinced on several occasions, and during several periods, in which the former have prevailed. Instances of both diseases occurred in the winter and spring of 1823 and 1830, and of almost every intermediate year. But cases have also been observed of either malady without the other; and, while infantile erysipelas has occasionally been seen contemporaneously with the appearance of puerperal fevers among the women, the former has not infrequently been met with when the latter did not exist, either sporadically or endemically.

152. Dr. HOLMES notices, in his instructive memoir, that Dr. S. JACKSON went from a case of gangrenous erysipelas which he had been dressing to the first of the series of cases which took place in his practice; and that a Dr. C., who delivered seven women in succession, who were all seized with puerperal fever, had made, on the 19th of March, the autopsy of a man who died after a very short illness, from oedema of the leg and thigh followed by gangrene, and the first of these seven cases was delivered by him on the 20th, the following day. When making the autopsy on the 19th, Dr. C. wounded his hand, and was confined to his house, after delivering the first case on the

20th, until the 3d of April, and on April the 9th he attended the second case of fever. "Several cases of erysipelas occurred very soon afterward in the house where the autopsy of the man just mentioned took place. There were also many cases of erysipelas in town at the time of the puerperal cases. The nurse who laid out the body of the third puerperal patient was taken on the evening of the same day with sore throat and erysipelas, and died in ten days. The nurse who laid out the body of the fourth case of puerperal fever was seized on the day following with symptoms like those of that case, and died in a week, without any external marks of erysipelas."

153. Another physician, who had a series of five successive cases of puerperal fever, states, in a letter to Dr. HOLMES, that for two weeks previously to the first case of puerperal fever he had been attending a severe case of erysipelas, and the infection may have been conveyed through him to the patient, as he admits; but, he asks, "Wherefore does not this occur to other physicians, or to himself at other times; for he has since had a still more inveterate case of erysipelas, but he has had no disease in any of his midwifery cases?" It would be culpable in him to make the experiment, or to repeat the risk, without due precautions. Inoculation with the matter of smallpox or cowpox does not always communicate the disease; indeed, it often fails of doing so; but no one now disputes the contagious nature of the virus inoculated. Dr. MERRIMAN, an able and cautious practitioner, mentioned (*Lancet*, 2d May, 1840) that he was at the examination of a case of puerperal fever at 2 P.M. *He took care not to touch the body.* At 9 o'clock the same evening he attended a woman in labour; she was so nearly delivered that he had scarcely any thing to do. The next morning she had rigours, and died in forty-eight hours. Her infant had erysipelas, and died in two days. A patient whom I was attending in the hospital, in 1828, was seen by a lady; and, while listening to her faint voice, her breath was felt by the lady, who was stooping over her. This lady was the following day attacked with erysipelas in the face.

154. Dr. RIGBY states that, in one epidemic in the General Lying-in Hospital, the child of every woman who died of the disease perished of erysipelas, which ran its course in a few hours. Dr. RAMSBOTHAM remarks, respecting this topic, that the cases recorded by CEELY and INGLEBY are so strongly in point, as to render it almost impossible to withhold the conviction that there is a form of fever to which puerperal women are liable, not only arising from the contagion of erysipelas, but, in its turn, also occasioning that disease in other persons. Whether in this affection, when it arises under such circumstances, the peritoneum is always attacked, is a question which he believes may be answered affirmatively in the great majority of cases. He further states, that on three occasions he has known the women who have nursed patients that died of this fever attacked with erysipelas of the leg; that in 1841, when erysipelas was prevalent in Roth-erithe, a medical friend of his had six cases, and while attending these he delivered a lady, who was speedily seized with puerperal fever,

and very soon afterward died. Her nurse was attacked with erysipelas of the hand, and was attended by another surgeon. One day, after having made an incision and dressed the wound, this latter surgeon was called to a case of midwifery: puerperal fever supervened, and the patient sunk very rapidly. A third fatal case, attended by the same practitioner, Dr. R. also saw, and others that did well. The disease disappeared in that vicinity when these practitioners declined to attend women in labour. Since the appearance of the second edition of his work, Dr. R. has met with additional facts, which he has had the kindness to communicate to me. A surgeon, in Clerkenwell, had five fatal cases of puerperal peritonitis, rapidly following each other, and two others, which Dr. R. saw, and both recovered; but both the children of these two latter cases died of erysipelas. One of the nurses in these last cases also took erysipelas. When this surgeon attended the first case of puerperal fever, he was just recovering of an attack of diffuse inflammation of the cellular tissue, with abscess of the fore-arm, consequent on having pricked his finger in opening the body of a woman who died of cancer of the uterus. Dr. R. concludes with believing, that "the connexion between malignant puerperal fever—that is, the fever in which the peritoneum is the seat of disease, and which terminates in the rapid effusion of soft lymph and whey-like serum into the cavity—and erysipelas is perfectly established." I may add to the above my opinion that the evidence is altogether satisfactory; that some of the series of cases of the more malignant states of puerperal fever have been produced by an infection originating in the effluvia proceeding from erysipelas, or by the contagion of the matter or contaminating material produced by erysipelas. It is quite unnecessary for me to adduce farther facts in support of this inference, but they may be found in the writings of CEELY, ACKERLEY, RIGBY, S. JACKSON, HOLMES, INGELBY, PALEY, STORRS, NUNNELLY, and numerous others, referred to in the *Bibliography* to this article. My opportunities of observing this disease since 1812, and what I have seen of it in hospitals and in private practice, have convinced me of the propriety of the following *inferences* and *precautions*.

155. *a.* That lying-in hospitals and wards have been established and supported on mistaken views as to the benefits they confer on individuals and the community; that the charity would be bestowed more safely to the objects themselves, and to others contingently, if it were so administered as to afford the required aid, to increase the comforts, and to improve the sanitary conditions of females in the puerperal states at their own places of residence.

156. *b.* If these institutions be still continued and supported, as introductions to midwifery practice, or for the doubtful benefit of the recipients of a certain kind of charity, the obstetric physicians and surgeons attached to them ought not to attend those cases of puerperal fever or of erysipelas which so frequently break out in the wards of such institutions; for, by doing so, they convey the poison from one patient to another, both within and without the institution. In all such circumstances, the consulting physician or surgeon to the institution, who, as

in my own case, should not be engaged in the practice of midwifery, ought to take charge of these cases, which should, immediately upon their attack, be removed, with due care and precaution, into a separate ward, provided for the reception of such cases, and situated without the walls of the hospital, but apart from other houses.

157. *c.* A physician or surgeon engaged in obstetric practice, upon the occurrence of puerperal fever in any of his cases, should either explain the matter to her friends, and call in a physician not engaged in this practice, to whose care she ought to be committed; or he should relinquish the care of puerperal females during his attendance on cases of this fever, and even of erysipelas; or he should change all his clothes, and carefully wash his hands, after seeing cases of either of these maladies, before proceeding to a puerperal female.

158. *d.* An obstetric practitioner should not make an autopsy of a case of puerperal fever, or of erysipelas, or of peritonitis, or of diffusive inflammation of the cellular tissue, or of the disease occasioned by the necroscopic poison (*see art. Poisons*, § 487, *et seq.*), nor even attend, or dress, or visit any of such cases, without immediately afterward observing the precautions just stated, and allowing two or three days to elapse between such attendance and midwifery engagements, or visits to puerperal females, [and even where these precautions have been strictly observed, we have known the disease to be communicated by the physician to his lying-in patients.]

159. *e.* It is the duty of obstetric practitioners attached to public institutions to prevent, as far as possible, the spread of this pestilence by midwives, nurses, or other assistants; and, as soon as two or three cases occur in succession, or other causes of suspicion present themselves, to take the most decided measures against the extension of contagion. Whatever indulgence may have heretofore been extended to those who have been the ignorant causes of the misery disclosed by the above statements—which convey but a small part of what has occurred in recent times—cannot now be expected, and ought not to be granted; for the practitioner is now too well informed, or, at least, the sources of information as to this matter are too open for him to be longer ignorant, that this most deadly of our domestic pestilences is conveyed from the infected to the healthy chiefly and most frequently by the accoucheur, when it occurs without the walls of a lying-in hospital, and that ignorance of, or inattention to, this fact, already not unknown to the well-informed part of the community—this flagrant neglect of what we owe to those who confide in us, and to society in general, to whom we must look for consideration and esteem—will be no longer viewed as a *misfortune*, but will be more justly considered a *crime* of no small magnitude.

160. *D.* What connexion is there between puerperal fever and other maladies, especially such as are epidemic or endemic? and may atmospheric vicissitudes or conditions be viewed as concerned in this connexion, and in their prevalence severally or collectively?—The infectious nature of puerperal fever has been demonstrated above (§ 140 *et seq.*), and it has been shown, as in Dr. MER

RIMAN's case, that the disease may be communicated without contact, although there is also reason to believe that the contact of a *materia morbi* will also convey it. The connexion between this fever and *erysipelas*, also a contagious disease, has next been shown (§ 151, *et seq.*); and it has been proved that the effluvia from a case of puerperal fever will produce *erysipelas* in a person predisposed to this latter malady, while that evolved from a case of *erysipelas* will occasion puerperal fever in newly-delivered females. Moreover, it has been shown by several cases in the course of my practice (to two of which I was called by one practitioner in the winter of 1827-28), that the infection of either this fever or *erysipelas* may be transmitted to females who are pregnant, more especially at a far-advanced period of gestation, and may rapidly produce premature delivery, followed by all the characteristic phenomena of malignant puerperal fever; while, on the other hand, abortion or premature delivery, particularly when either is accompanied with great hemorrhage or flooding, predisposes remarkably to the infection of puerperal fever, as well as to that of *erysipelas*.

161. The prevalence of *typhoid* or *adynamic* fevers have been considered by some writers as more or less connected with the occurrence of puerperal fever, and, indeed, that this latter is merely typhoid fever modified or aggravated by the puerperal state. We find that *smallpox* and *scarlet fever*, or *measles*, are remarkably aggravated, and the danger from them greatly increased, when they attack a puerperal female. But these diseases always preserve their identity and their specific forms, and the power of perpetuating or extending themselves. Their characters are not lost in those of puerperal fever; and if, during their course, the phenomena or the internal lesions and complications usually observed in malignant puerperal fever appear also in them, they are merely superadded, and become the causes of the greater malignancy and more rapid progress of the malady to a fatal issue. Now this has been the case also with the *true* or *exanthematic typhus*, when it affects a puerperal female, as far as my observation enables me to judge; for the characteristic eruption and the low, muttering delirium—the typhomania—marking this fever have also appeared in the puerperal manifestation or complication of it, the features of the puerperal malady being also present; the puerperal state imparting to this specific fever, as it does to the exanthemata, dangerous complications, more malignant characters, and a much more rapid and unfavourable issue.

162. I have had reason, however, to believe that puerperal fever may arise sporadically from the same causes as that form of fever which I have denominated *putro-adynamic*—the *putrid fever* of the older writers (*see art. FEVER*, § 484)—that fever, varying in its subordinate features, and in the lesions supervening in its course, may be produced in the puerperal state by the same causes as those which occasion that form of continued fever; that animal exhalations, the foul vapours from putrid animal matter and burying-grounds, the effluvia from privies and sewers, and the infectious emanations yielded by those affected by this fever,

will produce puerperal fever, in all respects the same as when it prevails in lying-in hospitals; and that the puerperal fever thus originating may be spread in the manner above demonstrated; that, in short, malignant puerperal fever may arise sporadically from those sources of infection I have described when treating of this property (*see INFECTION*, § 11, *et seq.*) and of the causes of *putro-adynamic fever* (*see FEVER*, § 449, *et seq.*, 484), and be transmitted from one puerperal female to another, when the circumstances favouring this transmission are present.

163. Dr. COLLINS states, that puerperal fever has become epidemic in the Dublin Lying-in Hospital on several occasions when typhus fever prevailed in that city, and at other periods when *erysipelas* was frequent. A patient was admitted at a late hour labouring under fever with petechial spots over the body. She was removed to a separate apartment, and died soon afterward. The two females who occupied the beds adjoining hers were attacked with puerperal fever and died. A patient in fever was admitted at night into one of the labour wards, where she remained for some hours. This ward contained four beds. The three women occupying the other beds were attacked with puerperal fever, and two died. Dr. COLLINS adds, that the recovery of the patient attacked with typhus fever at the *full period* of pregnancy is an interesting fact, as he believes that no complication proves more generally fatal than the premature expulsion of the child under such circumstances.

164. The prevalence, also, of the low types of the exanthemata, of rheumatism, and even of other diseases, which are favoured more or less by humid, stagnant, and cold states of the atmosphere, may exist contemporaneously with that of puerperal fever; but in such circumstances the only connexion subsisting between them is to be ascribed to the atmospheric conditions, especially those just stated, probably also associated with certain electrical conditions of the earth's surface and of the air, and with emanations from the various sources of impurity and of infection with which all crowded localities, towns, cities, factories, &c., abound more or less, particularly when these emanations are not swept away by high winds and due ventilation.

165. iv. DESCRIPTION.—*Puerperal fevers* present certain *types* or *forms*, depending chiefly upon the following circumstances: 1st. Upon the intensity or concentration of the exciting causes, relatively to the predisposition of those exposed to their operation; 2d. Upon the degree of depression of organic nervous energy or powers of life produced by those causes; 3d. Upon the extent of contamination of the circulating fluids consequent either on the respiration of a foul or infected atmosphere, or on the absorption of morbid matters from the sexual organs, or from other parts; 4th. Upon the continued operations of these, or of various concurrent causes and influences, during the progress of the malady; 5th. Upon the states of season, weather, and epidemic constitution at the time cases of this malady occur; and, 6th. Upon the manner in which the infection is produced, and the media or channels by which it is conveyed, when the disease is propagated by infection or contagion, as shown above

(§ 140, *et seq.*). These circumstances, aided by constitutional peculiarities, the previous conditions of organs and functions, and the morbid tendencies of the patient, are also the chief causes of the complications, ultimate changes, and results observed in the advanced course and at the termination of the malady.

166. The various arrangements of the forms of puerperal fever adopted by medical writers have involved the following important questions, namely: (a) *Are the several forms or types of puerperal fever the consequences of local changes—of those lesions observed after death; or, in other words, are they merely symptomatic disturbances of the constitution produced by these lesions?*—(b) *Are the structural lesions or prominent changes found on dissection produced in the course of the malady, and are they the ultimate results of that malady?*—(c) *And are these forms or types different from their commencement, and the effects of different grades of intensity of the exciting causes, and of the different avenues or channels by which these causes invade and poison the frame?*

Now the solution of these important questions has been eschewed by all writers, and even by the obstetrical writers on this malady, many of whom have mystified, rather than enlightened the subject. The answers which may be given to these questions will appear more illustratively in the sequel, for the importance of the topics to which they refer is great, not merely as respects an accurate description of the different resulting forms and states, but also as regards the adoption of appropriate prophylactic measures and rational indications of cure. The discussion of this topic cannot, therefore, be neglected with propriety. It is necessary first to advert to the modes and avenues by which the poison or infection may contaminate the frame, as above demonstrated (§ 143, *et seq.*). 1st. The atmosphere of a ward may be infected by animal effluvia—by exhalation from decomposed discharges, &c., as there shown; or a puerperal female may inspire the poisonous effluvia absorbed, retained, and afterward given out by the clothes of the medical attendant or nurse. In these cases the frame is infected through the respiratory avenue; organic nervous power and the circulating fluids being thereby morbidly impressed or affected. Whatever local changes or prominent lesions are observed after death, whether implicating the peritoneum, or the sexual organs, or other parts, are, in such cases, *consequence* of the operation of the exciting cause upon the nervous and vascular systems, and upon the blood. In these there can be no doubt as to the local lesions being consecutive of the infection thus produced; although the mode in which the consecutive lesions or complications are developed may admit of discussion, as noticed hereafter (§ 245, *et seq.*).

167. 2d. It has been shown above (§ 137, *et seq.*) that the poison may be conveyed to the uterus or vagina by contact—by the hands of the accoucheur; or the poisonous miasms or vapours exhaled from foul privies frequented just before delivery—a gust of foul air on those occasions—may infect the vagina and os uteri; or the decomposition of coagula in the vagina or uterus, or of a portion of a retained placenta may so contaminate these parts, the imbibition and absorption of the decomposed matters,

or of ichorous or puriform secretions in these situations, affecting not only the state of vital power and resistance, but also changing the constitution of the circulating fluids in such a manner as to give rise to all the phenomena and complications of this malady. In this latter mode of infection—and through the channel or avenue now stated—the local changes in the sexual organs are, as respects their earlier grades, the first to be developed; although they subsequently increase in extent and intensity with the depression or exhaustion of vital power, and with the contamination of the circulating fluids; and progressively extend to the peritoneum, digestive organs, heart, and other remote parts, as hereafter described. In the first of these modes of infection (§ 166) the local alterations are generally *consecutive* of the constitutional affection; in the second they are *primary*, but of such a nature as rapidly to contaminate the whole frame, and as to become themselves quickly aggravated and extended by the consequent constitutional infection. The former of these modes is produced by an extrinsic cause or poisonous emanation generally conveyed through the medium of the respired air; the latter by the contact of a material poison either directly applied to the prominently diseased parts, or affecting them in the manner already stated (§ 129).

168. It may, however, be admitted that, when the frame of a puerperal female is infected by a foul air, generated either in a lying-in ward, or in an apartment by privies and sewers, &c., and when vital power is thereby depressed and the circulating fluids contaminated, the secretions or discharges from the uterus will then also become altered, more or less acrid or otherwise morbid, and thus infect the parts with which they are in contact. Nor will the local alteration, thus originating, be limited to these parts, but it will extend to adjoining parts and surfaces, and even to remote situations, as shown in the *second* of the above categories; the complications or local lesions thus supervening upon the constitutional infection, and in their turn augmenting that infection. Such being the two modes of procession of the morbid changes, it becomes the more important to recognise the phenomena by which each is distinguished; and to inquire, as I shall endeavour to do in the sequel—as I have many years since inquired and acted, and not unsuccessfully—respecting the means which may be rationally employed to arrest the onward tendency of these changes to disorganization, to dissolution of the vital cohesion of the tissues, and to death.

169. 3d. Besides the two classes of cases now specified, and arranged according to the manner in which their efficient causes invade the economy and develop the malady, there is a *third*; and to this class may be referred those cases which evince a more strictly local character, which are more individualized in their manifestations and more limited in their tendencies and structural changes. These generally are *primary*, or commence with local changes of an inflammatory character, the constitutional disturbance being symptomatic of such changes, and varying with the state of the patient, and with the influences to which she is subjected. In this class the local affection is

more decidedly inflammatory; and if the diathesis be not altogether *sthenic*, it is at least much less *asthenic* than in any of the former classes. The cases in this third class may occur independently of any infection taking place in either of the modes, or by either of the avenues, indicated above; or, if they be produced at all, as there stated, the causes are so weak, or operate in such a manner as not materially to reduce vital power or resistance, or remarkably to lower the tone of vascular reaction. Some of these cases may be referred to causes productive of irritation or of determinations of blood to the affected parts; or to the suppression of the secretions and excretions; or to the nature of the ingesta, or to various other causes of visceral inflammation. If in any case either of the modes of infection above specified be concerned in producing this form of the disease, the infectious agent fails in occasioning the same amount of vital depression, of structural changes, and of general contamination characterizing the other forms, owing either to the relative weakness of this cause, or to the constitutional power and strong vital resistance of the patient. Keeping, therefore, in view the different or varying forms of the malady—the progressively malignant states of puerperal fever, with the nature, intensity, or concentration of the existing causes, and with their continued operation, I proceed to consider, *first*, the more local and *sthenic*, or inflammatory form or type of the malady, and afterward the more *asthenic* and malignant.

170. *A. INFLAMMATORY PUERPERAL FEVER.*—This form of the disease has been viewed by many writers as an *idiopathic* or *primary inflammation*, occurring in the puerperal state—as a *puerperal peritonitis*, or as *puerperal hysteritis* or *metritis*, or as *puerperal ovaritis*, according as the *peritoneum*, or the *uterus*, or the *ovaria* and *ligaments* are the chief seats of inflammatory action and of local change. That this form of the disease may thus occur primarily, being developed by causes which tend to localize disease, owing to their nature and channels of operation, must be admitted. Cold, humidity, neglect of various comforts and requisites, improper food or beverages, mental emotions, &c., may primarily excite either of these local diseases, and symptomatic fever, varying in the character or type of vascular action, with the state of constitutional power, and with numerous other concurrent influences and circumstances. But in other cases, as shown above (§ 169), the primary character of the local disease is lost in the intensity or severity of the constitutional disturbance; and the more prominent lesion of one or more of the parts just particularized, either is an attendant of the vascular reaction following the operation of the exciting causes and the shock produced by parturition, or is consequent upon the reaction, and is favoured by those conditions and circumstances insisted upon above as being influential in determining and localizing puerperal maladies (§ 10, 11, 41). When the common causes of inflammation occasion disease of one or more of these parts, the constitutional disturbance is modified more or less by the puerperal state, and by the constitutional powers and other circumstances of the patient. But as the infectious and contaminating effluvia in poi-

son, so influential in causing the malignant forms of the malady, has little or no share in the production of the sporadic or inflammatory cases constituting this form, they generally present more or less of a *sthenic* diathesis, and pursue a more favourable and less rapid course than the others.

171. (*a*) *PUERPERAL PERITONITIS.*—*Peritonitis Puerperalis.*—*Inflammation of the peritoneum* may occur in the puerperal state sporadically from causes already noticed, or even without any very obvious exciting or external cause. It may either be primary, or the consequence of the extension of irritation or inflammatory action from some one of the organs or parts seated in the pelvic cavity to that portion of the peritoneum enveloping the part thus primarily affected. This latter mode is probably the most frequent; for the uterus, the tubes or ovaria, owing to injury, to excoriation, or to the irritation of the lochia, or to other causes, may be so affected as not to betray the nature or amount of the affection, in consequence of the peculiar condition of the patient, until the disease extends to the peritoneum, and thus the parts primarily disordered are either overlooked or unrecognised, and the more prominent and secondary alteration attracts the chief attention, and is considered the only seat of the malady. This form of the disease is most frequently caused by violence during delivery, by exposure to cold, or damp or wet linen or bed-clothes, or by the use of improper food or stimulants. It may not appear for a fortnight or three weeks after delivery; but when it is the primary lesion it may occur on the second or third day, or earlier than inflammation of the uterus. Uterine hemorrhage predisposes to it as well as to the other forms of puerperal fever.

172. *a* *The symptoms of puerperal peritonitis* vary with the constitution, habit of body, and other circumstances of the patient and the mode of attack. The pulse often continues to rise in frequency from the appearance of the reaction consequent on the shock of delivery, and pain is felt in different parts of the belly, which are soon followed by chills, rigours, or shiverings. With these great increase of pain in the abdomen, with tenderness and tension, sickness or vomiting, is complained of. The pain is occasionally universal, but it is sometimes limited to one part, and the belly soon becomes swollen and tense. The pulse is frequent, hard or sharp, and small. The skin is hot; the pain and tenderness increase, and extend over the belly. The patient lies on her back with the knees raised. The tongue is white and dry; sometimes clean, or loaded only towards the root. There are more or less thirst, occasional vomitings, and an irregular state of the bowels, which are generally at first costive, but afterward often relaxed or bilious. The lochia and milk are much diminished soon after the rigours, and are subsequently entirely suppressed.

173. These symptoms often appear rapidly and acutely, especially when the peritoneum is primarily attacked. But they sometimes come on less severely and more insidiously, especially when they are consequent upon irritation or inflammatory states of the uterus or its appendages. In these cases, the disease may at first be mistaken for after-pains; but the fre-

quency of the pulse, tenderness above the pubes, the shiverings, and the swelling and tension extending upward from the hypogastrium, indicate the nature of the disease. When the malady thus commences the symptoms are milder and more protracted at first; and the pain for some time is not severe until it rises above the hypogastrium, when it is rapidly aggravated and extended, and all the other symptoms increased. Whether the early symptoms are rapid or slow in their accession, or whether they are limited or extended, they soon augment; the belly becomes nearly as large as before delivery, and so tender as not to tolerate the weight of the bed-clothes; and the patient is deterred from turning, or lying even for a few moments upon either side, by the increase of pain thereby caused. With the extension of the inflammation over the peritoneum, the respiration becomes more strictly thoracic, and the movements of the abdomen less apparent; and when it reaches the diaphragm the breathing is difficult, anxious, short, and performed entirely by the intercostal muscles. Cough then sometimes occurs, which is short, suppressed, and painful. Painful eructations, or belchings of flatus, take place at intervals, attended sometimes by discharges of fluid from the stomach. The bowels, which were generally confined, become more relaxed, and dark, bilious, or variously coloured evacuations, or even purging supervene.

174. *β.* If a favourable termination is likely to occur, the abdominal swelling does not greatly increase. The pain either is arrested in its extension, or it gradually abates. The vomitings cease, the pulse becomes slower and fuller, the urine more abundant, and occasionally the lochia reappears, or is more copious. The breathing is easier and more abdominal, pressure is less painful, and the patient can turn more easily in bed. In rare and less favourable cases, the disease terminates in suppuration, and the abscess points and bursts externally at periods more or less distant from the attack, the matter in some such instances passing out at the umbilicus in about one or two months.

175. *γ.* If the disease proceeds unfavourably, the swelling and tension of the abdomen increase; the belly is round and prominent; the vomiting continues or becomes peculiar, consisting of a pumping or belching up of the contents with much flatus. The countenance becomes sharp, anxious, or pinched; the pulse still more rapid and irregular; and her slumbers short, unrefreshing, and sometimes attended by a wild or wandering delirium; but she often continues sensible to the last. The pain frequently ceases suddenly, although the abdominal swelling increases; the countenance sinks; the extremities become cold, and the tongue apthous. A fatal issue usually takes place within five or six days; but the disease may be protracted much longer. According to the constitution and other circumstances of the patient, and the period that has elapsed from delivery, puerperal peritonitis may vary between the forms described as sthenic and asthenic peritonitis, when treating of *inflammations of the peritoneum* (see § 19–28), the symptoms and progress of the malady being altogether the same as there described. *The appearances on*

*dissection* are also the same as there stated, (§ 80, *et seq.*), or as exhibited hereafter (§ 221, *et seq.*).

176. (*b*) **PUERPERAL METRITIS.**—*Hysteritis Puerperalis.*—*Inflammatory puerperal fever often commences in the uterus*, the substance of the organ being affected about the third or fourth day after delivery, but often much later. It may arise from prolonged, difficult, or instrumental labour; from cold or damp; from stimulants or heating food; and from other predisposing and exciting causes already noticed.—*a.* The symptoms vary much with the severity of the attack, and with the extension of the inflammatory action to the uterine peritoneum on the one hand, and to the ovaria and ligaments on the other. It thus assumes mild or severe forms, the progress of which is modified by the rapidity of the extension just mentioned. The milder states of *hysteritis* usually commence from the fourth to the ninth day, and much resemble the ephemeral fever. The patient is chilly or shivers, is sick, and sometimes vomits. The pulse is frequent and soft; and with the establishment of reaction, pains, which were occasionally felt in the hypogastrium, and which were, perhaps, only considered to be after-pains, become more constant, but are not severe. They are usually felt behind the pubis; but they may extend a little to either side, or towards the groin. Pain is also sometimes felt in the back, especially if the patient attempts to sit up. It may not be complained of even in the hypogastrium, when she lies still; but it is usually felt when turning to either side, or when pressure is made above the pelvis. There is no fullness, hardness, or tenderness of the abdomen. The lochial discharge gradually diminishes; but it does not necessarily stop; and the milk sometimes continues plentiful. The skin is hot; there are more or less thirst, no appetite, sickness at stomach, and disturbed sleep. The pulse varies from 90 to 110; the head is confused rather than painful; the urine is high-coloured; the bowels confined, and wandering pains are felt in the belly and sides. The bowels afterward become loose or irregular, the stools being dark, offensive, or morbid. Strangury, frequent calls to pass the urine, pains in the hips, and hearings down on micturition are often complained of. In the course of a few days, sometimes not until ten, twelve, or fourteen days have elapsed, the pulse becomes slower, the appetite returns, the painful symptoms referred to the uterine region subside, occasionally a slight discharge takes place from the womb, and the disease entirely disappears. Sometimes, however, the patient continues to experience more or less disorder referable to the uterus, with or without slight alterations of the position of the organ, until the menstrual discharge is fully established, when it subsides.

177. *b.* The more severe form of *hysteritis* is often caused by difficult parturition, by rude management, or by other more intense causes. It usually commences between the second and fifth day, but it may appear at a later period. It is ushered in by chills or rigours, which are often present, although the skin is hot, and which are generally preceded by pain in the lower part of the abdomen. With the appearance of reaction and of the febrile symptoms,

the pain becomes more constant and severe, but is usually characterized by exacerbations. The uterine region is very painful on pressure just above the pubis, and in this situation there is generally some swelling, which, however, does not extend farther until the peritoneum is affected. The abdominal parietes is slack or soft, so as to admit of the state of the fundus of the uterus being ascertained. The uterus is larger, harder, and much more sensible than usual. The pain extends to the back, shoots to the groins and hips, is attended by a sense of weight, and by difficulty of passing the urine. Occasionally there is distressing strangury, or complete suppression of urine. The lochial discharge is early suppressed, and the secretion of milk diminished or arrested. The temperature of the vagina is increased, and the sexual and urinary organs feel generally hot, inflamed, painful, and tender, the situation of the pain at the commencement varying with the part in which the inflammation originates. With the development of the local malady the symptomatic phenomena become prominent and severe. The pulse is very frequent, somewhat hard, or sharp; the skin is hot; thirst is increased; the tongue is white or dry; the urine high-coloured and scanty, or turbid; the bowels are at first confined, but afterward lax or irregular; headache is present; the countenance expresses suffering, but it is not collapsed or constricted as in peritonitis; and nausea and vomiting are urgent. Sometimes the internal surface or part of the womb is chiefly or only affected; and in this case a puriform discharge follows the diminution or suppression of the lochia.

178. *c.* If the inflammation do not extend over the peritoneum, a *favourable issue* is more likely to take place than in any other form of puerperal fever. This *termination* often is preceded by a copious perspiration, by diarrhœa, or by uterine hemorrhage, which is the most complete crisis. The abatement of pain and of the febrile symptoms; diminished frequency of the pulse; the reappearance of the lochia and of the milk; a free and general perspiration; a more natural state and excretion of urine; cessation of nausea and vomiting, and a more natural state of the bowels, are the surest signs of a favourable result.

179. *d.* An *unfavourable termination* of this form of the disease is to be feared when the inflammation extends either to the peritoneum or to the uterine appendages, or when it goes on to suppuration, either of the substance or sinuses of the organ.—*a.* If it extend to the *peritoneum*, the local symptoms, especially the pain and tenderness in the hypogastrium, advance upward, and gradually invade all the abdomen, or sometimes only the lower regions; and swelling, tension, and tenderness of the belly, with all the symptoms of *peritonitis* (§ 172, 173), supervene and *complicate* the metritis.—*β.* If this latter go on to *suppuration*, the pulse becomes still more frequent, fuller, softer, and afterward weaker, or more compressible, and smaller. The tongue is red or dry; the pain does not materially abate, but it becomes throbbing; chills or shiverings are sometimes experienced; and in the absence, or consecutive of these, copious sweats break out at intervals. The face is paler, or is more sharp than be-

fore, and occasionally a circumscribed hectic flush appears in the cheeks. The urine now deposits a pink sediment. The nights are sleepless, and, if the patient slumbers towards morning, she awakens in a profuse sweat. This suppurative form of hysteritis may prove early fatal; the pulse increasing in frequency, the tongue being red and raw, and the strength sinking; or the hectic symptoms may continue for weeks, and at last be fatal. Occasionally matter is discharged from the vagina, or by the bladder or rectum—oftener by the rectum. When it passes by the vagina the patient may recover; but when it passes by the other channels recovery more rarely occurs. It may break into the peritoneal cavity and produce fatal peritonitis.—*γ.* When metritis becomes associated with inflammation of the *ovaria, ligaments, and tubes*, the symptoms about to be mentioned supervene at an earlier or later period (§ 182).

180. *c.* The *appearances on dissection* depend upon the direction the disease takes towards the fatal issue. If it has terminated by fatal peritonitis, the usual alterations produced by that malady are found, sometimes with more or less softening of the uterus, or with sero-puriform infiltrations or purulent collections in the walls or in the sinuses of the organ, occasionally also in the veins and absorbents in the vicinity. If the disease has not extended to the peritoneum, but has terminated by suppuration, these latter changes are the more remarkable; and no farther disease of this membrane may exist beyond some alterations of the portion covering the uterus and appendages, consisting chiefly of exudation of lymph, with little or no serous effusion, but often with puriform infiltrations or collections underneath the peritoneum, and softening of the tissue. Gangrene or sphacelation is rarely observed, unless the autopsy has been delayed longer than twenty-four hours.

181. (*c*) **PUERPERAL INFLAMMATION OF THE UTERINE APPENDAGES.**—It is comparatively rare to find, either during life or on examination after death, the ovaria, broad ligaments, and tubes inflamed independently of peritonitis, or of peritonitis associated with hysteritis, in the more *inflammatory form* of puerperal fever. In the more *synchoïd* and *malignant states* of this fever, the uterine appendages are very frequently the seat of lesions hereafter to be described; but they are, perhaps, never found in these latter states affected alone; the peritoneum or the uterus, or both, and often several other structures, being also more or less altered. It is only in the inflammatory or more sthenic form of puerperal fever that these appendages are affected alone, or chiefly, and then only in rare instances. Even when the disease appears to originate in these, which is not unusual, it soon extends to the peritoneum; and, if it preserve its sthenic character, it does not spread much farther than to the portion of the membrane adjoining; but if the asthenic condition exist, or if vital power become depressed, or the blood contaminated by the absorption of matters from the uterus or vagina, the disease soon spreads from the uterine appendages over the peritoneum, if it be not arrested in its progress by treatment.

182. *a.* The *symptoms* of inflammation of the uterine appendages, whether the affection ori-

ginates in or extends to these parts, are generally ushered in with rigours, and with pains, tenderness, and fullness in one or both sides of the hypogastrium, extending to the groins, the pains generally shooting down the thighs. As vascular reaction is established, the pulse becomes rapid, the skin hot, the urine scanty, high-coloured, &c.; and headache, thirst, diminished or suppressed lochia, suppression of the milk, and other symptomatic phenomena appear. An examination *per vaginam* evinces increased heat and tenderness at the upper part of the canal, and in some cases even a tumour may be felt laterally. When the disease extends to the peritoneum, pain, tension, fullness, and exquisite tenderness advance upward; and all the symptoms of *peritonitis* supervene, sometimes with others more strictly appertaining to *hysteritis* (§ 176), with which the inflammation of the uterine appendages may be associated, as either the primary or consecutive affection.

183. *b.* The terminations of the inflammation of the uterine appendages are, 1st. In *resolution*, which may take place, as in cases of metritis, without any permanent injury being sustained. 2d. In *adhesions*, by the medium of coagulable lymph to adjoining parts, which, by their situation or extent, may be injurious at some future period. 3d. In *obliteration of the Fallopian tubes*, and the consequent loss of function, or sterility, which ensues. 4th. In *suppuration*, the matter forming either in the ovary, or in the broad ligament, or in the veins. The purulent collections or deposits may exist in these situations in various forms, the patient dying of the attendant softening and disorganization of the adjoining parts and of the purulent absorption, but most frequently of the consequent or associated peritonitis, and more rarely of the complication with metritis. A large collection of matter in these parts may burst into the peritoneal cavity, or may open into the vagina, or into the rectum, or through the abdominal parietes, near *POUPART'S* ligament. The appearances on *dissection* are described in the article *OVARIA*, and in the sequel (§ 229).

184. *B. SYNOCHOID PUERPERAL FEVER.*—*Consecutive Puerperal Fever.*—This form of the malady is that most frequently observed both in private practice and in lying-in wards, unless the causes be intense or concentrated, and then the disease assumes a more malignant character. This form may be sporadic, or endemic, or even epidemic, especially in lying-in hospitals; and in these, as well as elsewhere, it assumes modified states of vascular action and local affection, according to the constitution and other circumstances of the patient, to the relative intensity of the exciting cause, and to the avenues through which this cause affects the frame. Hence it presents, in different cases, every modification, from the inflammatory to the malignant. The same causes, or combinations of causes, as infectious miasms, transmitted by the medium of the surrounding air, or contagious fluids or secretions conveyed by the hands of the accoucheur, aided by concurrent influences, may, in the same ward, or in other places, produce this form of the malady in one female, and the malignant form in another; the state of the female, the period that has elapsed from delivery, the predisposition resulting from uterine hemorrhage, &c., remarkably favouring

the intensity and character of the attack. Thus I have seen in the same lying-in ward, and even in contiguous beds, cases not only of this form, but also of the most malignant form of the malady, each presenting different prominent affections: one peritoneal disease chiefly, another very remarkable uterine affection, a third prominent alteration of the uterine appendages and peritoneum, and in a fourth inflammation of the veins or lymphatics of the uterus and its appendages, or of both these vessels. This occurrence, and the circumstances connected with it, indicate two things, namely, the spread of the disease owing to the operation of a cause infectious or contaminating in its nature; and the production of different local alterations, in different cases, in connexion with the infection and contamination of the constitution; of the nervous and vascular systems, and consecutively of all the living structures.

185. *a.* The symptoms of this form of puerperal fever vary with the circumstances already noticed, and with the mode of its accession. In many cases the *uterus* is the first to be attacked; in some the *uterine appendages* are the first to manifest pain, tenderness, &c.; in others the *peritoneum* appears to be primarily seized; and in a large proportion alterations exist chiefly in the *uterine veins*, with more or less lesion of other parts. The mode of accession of the disease is no less varied than the local lesions discovered after death; and neither it, nor the progress of the symptoms subsequently, can always be strictly attached to the several states of the malady so as to indicate them truly during life. The accession of pain is often sudden, and as often insidious, appearing as after-pains, or as an aggravation of these, or merely as the increased sensibility of the uterine organs usually consequent upon parturition. It is frequently attended by chills or rigours, or by a recurrence of these; or the chills may be so slight as to escape observation. In the more robust, and when the powers of life are not remarkably depressed by the exciting cause, the shiverings are often severe; and in these reaction is usually more fully developed, and the disease more nearly approaches the inflammatory or sthenic form. As the chills disappear, the pulse, which was already frequent and small, becomes more frequent and fuller; but still soft, open, and compressible. The skin is hot; thirst, nausea, and vomiting are complained of, sometimes with cough, vertigo, or pain across the forehead. Soon after, or almost instantaneously with these symptoms, pains in the abdomen are experienced, in various degrees of severity; and the patient lies on her back, with the knees drawn up.

186. *b.* If the local disease commence in the *uterus*, the pain and tenderness on pressure are first felt in the region of the uterus, and the abdomen, above this region, is soft and flaccid. The body of the uterus is enlarged; and the pain, frequently at first recurring in paroxysms, or presenting exacerbations, is often mistaken for after-pains, until pressure indicates great tenderness, and discloses the nature of the attack. With the aggravation of the fever, the countenance becomes suffused and the respiration hurried. With the extension of disease from the uterine peritoneum to the rest of the membrane, the pain and tenderness extend up

ward over the abdomen, which becomes swollen, tympanitic, acutely painful, and tender. Vomiting of dark-coloured or greenish fluids ensue, often attended by diarrhœa, the stools being dark, offensive, and watery. The pulse soon becomes remarkably rapid and feeble, sometimes irregular; the tongue brown or dry, the teeth covered by dark sordes; the countenance sunk and pallid; the breathing short, laboured, and intercostal, with a short, suppressed cough, singultus, and eructations of flatus, with which more or less dark fluid is thrown up, without retchings. Coldness of the extremities, remarkable smallness and frequency of pulse, and a cold and clammy surface, with a short, gasping respiration, usher in dissolution, the mental faculties being often but little disturbed.

187. *c. If the local alterations commence in the uterine appendages* the symptoms generally are but little different from those just stated. Pain, tenderness, and fulness are first felt in either or both sides of the hypogastrium, instead of behind or immediately above the pubis, as when the disease begins in the uterus. The primary affection, however, may be seated in the uterus, without being detected, and extend to the appendages, or both to the uterine peritoneum and to the appendages, and thence, more or less, over the peritoneal cavity. In the early period of these cases, the abdomen may remain for a short time flaccid, and tolerant of pressure; but it soon presents all the symptoms just mentioned, with the severe constitutional infection, which rapidly increases and aggravates the local changes by sinking the powers of life and contaminating the circulation. When the peritoneum becomes implicated to a great extent, the symptoms above described are always present; and, if the disease be not arrested at an early stage, the fatal issue advances as there stated—the lesions observed after death being most remarkable in the uterine appendages, as will be shown in the sequel.

188. *d. That the prominent alterations so frequently seen in the peritoneum* actually originate in it cannot be doubted, in respect of some cases of this form of the disease; for the seat of the early symptoms and the appearances on dissection are not sufficiently demonstrative of a primary affection of the uterus or of its appendages. Nevertheless, it may be admitted that a local poison or a contagious fluid may affect the internal surface of the uterus, and that the change which takes place primarily in this part may be extended along the tubes to their fimbriated extremities, and thence over the peritoneum, the symptoms of the early lesions not being fully developed, or escaping observation, until the peritoneum is extensively implicated. When this membrane is thus primarily attacked, the pain generally commences at the epigastrium or about the umbilicus, is sudden and acute, and is attended by extreme intolerance of pressure, tympanitic distention of the abdomen, a rapid pulse, and vomiting; these symptoms being generally ushered in with chills or rigours, which may either precede or accompany the pain and tenderness of the belly. In some cases the chills or rigours are either slight or of very short duration, and may thus escape notice; but they are seldom ab-

sent altogether in this state of the disease. The pulse is always quick from the commencement, and even before either pain or rigours are experienced. The lochia and milk, in this as well as in the other states of this form of puerperal fever, are either diminished or suppressed from the appearance of the rigors. The urine is always high-coloured and very scanty, or even suppressed; the bowels irregular, the stools at first lumpy, afterward relaxed, watery, dark, and offensive; and the tongue white or parched, subsequently dark or brown. The countenance is anxious and collapsed, the respiration short, quick, gasping, and thoracic; and, during the advanced progress of the malady, the acute pain and tenderness of the abdomen subside with the supervention of fluid effusion into the peritoneal cavity; and the tension subsequently also subsides, the abdomen often being very tumid, but soft and swaggy. All or most of the symptoms accompanying an unfavourable termination of the other states of the disease now supervene with a rapidity varying with the severity of the attack and with the degree of vital power attending it, or of vital resistance opposing the occurrence of dissolution.

189. *e. Inflammations of the veins of the uterus and its appendages, sometimes of the lymphatics, and, in rare instances, of both orders of vessels,* are frequently the primary and essential alterations in the form of puerperal fever now under consideration; but they are not the only changes, especially in fatal cases; for, in these especially, various consecutive lesions, of an extensive and disorganizing kind, are also found on dissection, or even become very manifest before death. *Uterine phlebitis* is most commonly observed in the puerperal state; but it may occur, independently of this state, in consequence of ulceration of the os or cervix uteri, or of ulceration consequent upon the presence or removal of polypus. It is caused in child-bed by the usual circumstances and influences which occasion other inflammatory diseases in persons weakened or exhausted by prolonged suffering or by losses of blood, these conditions, especially flooding and difficult or instrumental labours, the depressing emotions, and a varicose state of the veins, favouring the occurrence of phlebitis. The chief or essential cause is undoubtedly the circumstance of the vessels of the uterus being placed, by the separation of the placenta, in an analogous state to the wounded surface of a limb after amputation. The irritation occasioned by an adherent portion of placenta, or by the decomposition of it, or of coagula which have not been thrown off, owing to the imperfect contractions of the uterus after delivery, is often a cause of this state of the disease. Injury, also, sustained during delivery, and alterations or decomposition of portions of the retained lochia, may either inflame the sinuses or veins, or may contaminate the blood in them, the portion thus contaminated farther changing the circulating fluid, and even affecting the vessels through which it passes. The disease of these vessels may, however, be produced by the contact of an infectious fluid, or by the changes occasioned in the lochia by the foul air to which this discharge may be exposed, as shown above (§ 137, *et seq.*).

190. *a. Uterine phlebitis* generally commences

in the vessels which have become in some respects exposed by the removal of the placenta, as shown by the frequent limitation of it to the vessels of that part or side of the uterus to which the placenta was attached. It often extends to the veins and sinuses of the greater part of the uterus, and to the veins also of the ovaria and tubes, but chiefly to those of one side, that side being the seat of attachment of the placenta, or principally its seat. Uterine phlebitis is often a simple or uncomplicated disease of the uterine organs, but it seldom continues any time without giving rise to various consecutive lesions, both of adjoining and of remote parts. When it is associated with inflammation of the internal surface of the uterus the phlebitis may be consequent upon this latter lesion; but when the substance of the uterus or the uterine appendages are also inflamed, it is difficult to determine which is primarily diseased. When thus complicated, the veins in some cases are most affected, and the substance of the uterus in others. In many instances, however, uterine phlebitis is associated with peritonitis, without the substance of the uterus being materially changed, or merely with slight softening; while in some there are not only phlebitis and peritonitis, but also extensive softening of the uterus and of the ovaria and ligaments. It is possible that the alterations of the sinuses, veins, and substance of the uterus may be nearly coeval; for if we admit the influence of injury, or of retained putrescent matters upon that portion of the uterus to which the placenta was attached, and upon the exposed openings of its vessels, the effects may be produced upon both the vessels and substance of the organ. But it cannot be disproved that inflammation may commence in either and be limited to it, or extended to the other, as circumstances may favour the extension.

191. Inflammation of the uterine veins generally extends to the veins of the tubes and ovaria; but those of the uterus may be inflamed on both sides, and yet the disease may extend only to the veins of one tube or ovary. M. DANCE states that the veins of the right tube and ovary are more frequently altered than those of the left. However extensively the veins of the uterus and appendages may be inflamed, the disease may be limited to these organs; but as frequently it is extended to their trunks, even as far as the hypogastric vein, or nearly to the vena cava. It may be asked, however, what are the changes which may be viewed as consequences of uterine phlebitis? and, should the presence of pus, merely in the uterine veins, be viewed as indicative of inflammation of them? The existence only of pus in the veins of the uterus is not sufficient proof that the pus is a product of inflammation of these veins, for the pus may have been imbibed by the veins from the cavity or internal surface of the uterus, where it had been produced by inflammation of that surface; and therefore, unless its existence be associated with changes in the coats of these veins, it cannot be viewed as a satisfactory proof of uterine phlebitis.

192. *β. The symptoms* of this form of puerperal fever—of uterine phlebitis—cannot be stated with the desired precision. Indeed, the accomplishment of the attempt is nearly impossi-

ble; for the change is so frequently and so early associated in puerperal females with alterations of the substance of the uterus and appendages, and not only with these, but also with changes in the peritoneum and in remote parts, that it is most difficult to separate the phenomena which belong to the phlebitis from those which are attached to the other lesions. The symptoms, therefore, of this form of the disease should be viewed as not strictly those of uterine phlebitis, but of that state of puerperal fever in which this particular lesion constitutes a more or less important part of the organic changes found after death. That this lesion is an important one in puerperal fevers is shown by the fact that pus and other changes in the veins have been found by M. TONNELLE in ninety-three cases out of two hundred and twenty-two, and in twenty-four cases out of forty-five by Dr. R. LEE. But in most of those cases in which it has been seen it was associated with other changes, as just stated.

193. Uterine phlebitis usually commences in from twenty-four to forty-eight hours from delivery, with pain in the uterus accompanying, preceding, or following rigours. The uterine region is tender on pressure, and upon the cessation of the shiverings and chills the lochia and milk are generally found much diminished, and if not altogether suppressed, they soon are. The pulse is frequent from the first, and general uneasiness, with physical depression, nausea, or vomitings, and headache are experienced. As the rigours cease, the skin becomes hot, the pulse more accelerated, but soft, often full, broad, and open, and the vomiting more frequent, a greenish fluid being usually thrown up. With the headache some degree of incoherence may be remarked in some cases, or delirium and agitation in others, which often pass into extreme exhaustion or a state of drowsiness or partial insensibility. Tremours of the muscles of the face and extremities, dysuria, or scanty or entirely suppressed urine, an irregular state of the bowels, or diarrhoea and offensive stools; extreme thirst, parched mouth, dry and brown tongue; a sallow, lurid, and dirty hue, occasionally with miliary or petechial eruption, and more rarely a dirty yellowish appearance of the whole surface of the body, generally supervene as the disease advances.

194. The pain in the hypogastrium varies in severity, but it may not increase with the progress of the malady, but the tenderness in this region is generally aggravated, and the abdomen is commonly swollen or tympanitic. If the phlebitis be associated with peritonitis, extreme pain and tenderness of the abdomen, great tension and tympanitic distention of the abdomen are experienced with all the symptoms attending the peritoneal state of the malady (§ 172, 173).

195. If the uterine phlebitis proceeds without being associated with inflammation of the pelvic or abdominal peritoneum, little or no pain in the hypogastrium may be complained of; or merely a dull pain, with a sense of weight. But this region will generally be found tender, or painful on pressure. The uterus, too, may return to its reduced volume, or nearly so if its substance be not implicated; but, if its substance be diseased, it commonly remains above

the brim of the pelvis, and is large, hard, and very painful on pressure. In many instances these local symptoms may be so slight as to escape attention, the constitutional symptoms caused by the passage of morbid matters into the blood, especially prostration of strength, feeble and rapid pulse, vomitings, and diarrhoea, low wandering delirium, brown parched tongue, diminished, suppressed, or puriform or offensive lochia, &c., at last exciting alarm, and indicating the existence of a most dangerous malady. A large proportion of cases terminate fatally in this more acute stage, or within eight or ten days; but a larger number live longer, some *secondary affection* supervening.

196. *γ*. The *consecutive affections* generally appear in remote organs, especially the lungs, pleura, brain, liver, spleen, the joints or muscles, the cellular tissue, the eyes, and digestive canal. One or other of these organs and parts, in the course of a few days, experiences a rapidly-disorganizing form of congestion or asthenic inflammatory action; softening, puriform, or sanious infiltrations, purulent deposits, and even gangrenous softening or liquefaction of the tissues, and effusions into serous cavities quickly following the secondary local affection, which is undoubtedly occasioned by the passage of the sanious and purulent matters into the circulation, and by the action of the contaminated blood on the capillaries of predisposed or susceptible parts. Many of these secondary affections advance insidiously, and without being attended with much pain or local distress until they reach the last stage of disorganization; while others betray much earlier, and by more evident symptoms, the nature of the consecutive mischief. Their progress, generally to a fatal issue, is often rapid; but not infrequently it is much slower, the duration of the malady depending on the seat and extent of the consecutive disorganization.

197. In this form of puerperal fever the inflammation may be limited to the veins of the uterus, but more frequently the muscular tissue adjoining the veins participates in it, and becomes of a dark-red or brown colour, and remarkably soft consistence; the peritoneal covering of the uterus may also be implicated, and the changes hereafter described be found in the appendages and peritoneum. The veins which return the blood from the uterus and appendages may be either wholly or in part inflamed; commonly, however, the spermatic are chiefly affected, and generally the one on that side of the uterus to which the placenta was attached; and it may be confined to a small portion of the vessel, or extend throughout it. Injection, infiltration, or condensation of the cellular tissue in which the veins are imbedded; thickening induration and constriction of the coats of these vessels; and the exudation of lymph, mixed with pus and coagula of blood within their canals, are the changes chiefly observed in fatal cases of uterine phlebitis. The hypogastric veins are more rarely affected than the spermatic. Dr. R. LEE ascribes this to the latter vessels being invariably connected with the placenta; but as in respect of the spermatic, so it is observed as regards the hypogastric, that only one is affected. Marks of disease of the uterine veins may extend by the iliae or the spermatic veins to the vena cava itself. "This

occurrence seldom takes place to a great extent through the medium of the spermatic; the inflammation usually terminates abruptly at the opening of the spermatic into it on the right side, or of the renal on the left. If it pursue, as it sometimes does, the direction of the kidneys, the substance of these organs, as well as their veins, may be involved in the disease."

198. *C. MALIGNANT PUERPERAL FEVER.—PUTRO-ADYNAMIC PUERPERAL FEVER.*—This most fatal form of the malady—most fatal if not very early, very decidedly, and most appropriately treated—occurs chiefly in lying-in wards, and in circumstances described above (§ 36-40, 140). It was the almost only form of the distemper observed in Queen Charlotte's Lying-in Hospital in 1823 and 1824, and until the improvements were made in the house. It is the most certainly infectious and contagious form of puerperal fever, being often conveyed by the clothes of the accoucheur or nurse. When this disease is produced sporadically by the foul or contaminating air of a close or crowded lying-in ward, or of a low apartment, liable to gushes of foul air from privies, sewers, or cess-pools, it is not infrequently conveyed to other puerperal females, as already shown (§ 137, 138); and it produces a similar, or but slightly-modified state of disease to that which transmitted the infection. In all its essential characters—as respects its exciting causes, the general depression of vital power, the rapid contamination of the circulating fluids and loss of the vital cohesion of the soft solids, &c., this disease very closely resembles *Putro-adyamic fever* (described at § 472, *et seq.*, of art. FEVER). The chief differences between them arise from the peculiar circumstances of the female at the time of infection; and to these are entirely to be imputed the rapid progress of the puerperal disease, the greater malignancy, if not early arrested by judicious means, and the local complications which frequently either appear during the course of the malady or are detected on examination after death.

199. *a*. The symptoms of malignant or putro-adyamic puerperal fever vary in the mode of their *accession* with the period of the puerperal state at which the infection appears to be produced. In three sporadic cases, to which I was called in consultation, the disease commenced in the last week or fortnight of pregnancy; and in two instances it either followed or caused abortion, for I was unable to determine the sequence; but as I traced, as I conceived, the disease in two out of the three sporadic cases just mentioned to the frequenting of privies having no communication with drains, and containing the accumulated exuviae of many years, it is not improbable that the abortion was the result of a local infection. When, therefore, the infection, poison, or contamination, however, or by whatever channel it may be communicated, attacks a female before delivery, or immediately afterward, or not until several days have elapsed from delivery, the *accession* of the early symptoms may be expected to vary accordingly.

200. (*a*) In a case of a female attacked *before delivery*, to which I was called by Mr. BARNWELL, the symptoms were the same as those observed by me in other cases. This patient was seized early on the 12th of February with acute pain throughout the abdomen, with enormous disten-

tion and exquisite tenderness ; with very rapid, full, and soft pulse, varying from 130 to 136, and with frequent vomiting. I saw her in the afternoon of the same day. The vomiting and state of the pulse were as now stated. She complained of headache and of thirst, and was very despondent. Her tongue was broad, flabby, slimy, and tremulous ; her countenance pale, anxious, and covered by perspiration, and her general surface moist, warm, and clammy. Labour-pains came on that evening, but were soon inefficient, the action of the uterus having ceased. Mr. BARNWELL administered *secale cornutum*, which ultimately induced uterine action, and she was delivered after a labour of about twenty hours. On the following day (the 16th) the distention and tenderness of the abdomen were diminished ; and the sickness and vomitings, with borborygmi and flatulent eructations, continued. A pathetic depression of spirits, anxious expression of countenance, flabby and slimy state of tongue, a very rapid, fluent, and weak pulse, clammy state of skin, scanty and almost suppressed urine, quick and oppressed breathing, a feeling of pressure on the diaphragm, requiring the head and shoulders to be elevated, were soon followed by the symptoms ushering in dissolution.

201. (b) When the disease follows *almost immediately upon delivery*, or soon after this event, the earliest indication of the impending mischief is the great rapidity, softness, and weakness of the pulse, often attended by pain and tenderness at the epigastrium, by sickness and vomiting, followed by general distention of, and pains darting through the abdomen ; but in the majority of cases there are neither chills nor rigours ; in a few, a feeling of coldness only ; and in still fewer, slight rigours. In this state of the disease the patient soon becomes despondent, predicts her dissolution, is afterward apathetic, and makes little or no inquiry for her infant. The milk and lochia are either little or not at all diminished, or are more than usually abundant. The abdominal pain and distention are sudden or quick in their accession, but the pain often soon ceases, the distention remaining, and afterward changing its character, if the disease continues above two or three days. The tongue, from the commencement, is flabby, broad, and slimy, or covered by a mucous or creamy coating ; the pulse is usually from 120 to 140, or even upward, fluent, soft, or broad ; and the general surface presents a lurid, or dusky or dirty hue, and is covered by a clammy and offensive perspiration. The countenance is pale and inexpressive, unless when the pain is acute, when it becomes anxious and covered by perspiration. The mind is but little disturbed beyond a state of complete apathy. As the disease proceeds, respiration is short, suspirious, or difficult ; the pulse small and soft, or irregular ; the bowels frequently relaxed, and the stools offensive and passed without control. Distressing feelings of sinking, leipothymia, or restlessness supervene, and are soon followed by the symptoms of impending dissolution.

202. (c) When the disease does not appear until *two, three, or more days have elapsed from delivery*, the abdominal pain, distention, vomiting, vital depression, and rapidity of pulse are very often sudden in their accession, and unattended by either chills or rigours ; much more

rarely they are more gradual, and attended by chilliness or slight rigours. But physical and mental depression, absence of hope of recovery, of all affection or care for the infant, and of regard for any object whatever, and perfect indifference, characterize this form of the malady at whatever period of the puerperal state it makes its appearance. In one case, which occurred in the hospital in 1824, the attack took place above a fortnight after the patient was delivered, and while I was in the board-room. When I was visiting some other patients about an hour before her attack, she was sitting in a chair by the fire-place making no complaint ; and after this short period I found her complaining of agonizing pain over the whole abdomen, with enormous tympanitic distention, extreme tenderness, and a pulse so rapid as hardly to be counted. Vomiting with eructations of flatus, leipothymia, cold, clammy, offensive perspirations, quick, short, and laborious respiration ; failure of the pulse at the wrist ; cold, clammy extremities ; moist, flabby, and tremulous tongue ; singultus, eructations or belchings of the contents of the stomach, and loss of power of the sphincters successively supervened, and terminated in death within twenty hours from the accession of the seizure.\*

\* The following case, recorded at the time, will illustrate this form of the malady. I adduce it, not as being characterized by extreme malignancy, nor by any marked peculiarity, but as a specimen of the disease as it was then prevalent, and as the treatment which had been adopted was such as could not have influenced the rapid tendency of the disease to dissolution. Mrs. TURNER, married, aged about twenty, was delivered on the 2d of February, after a natural labour. She was seized on the 11th, without any chill or rigour, with severe pain in the epigastrium, distention and tenderness of the abdomen, rapid, soft, and weak pulse, sickness, and vomiting. The matters thrown off consisted chiefly of greenish fluids, and the pain extended to the hypogastrium and both groins. I was not called to her until the evening of the 13th, about fifty-four hours after the accession of the disease. She then presented the following symptoms : The pulse was so rapid and weak as hardly to be counted or felt at the wrist ; the hands and feet were cold and clammy ; the breathing remarkably quick, difficult, and labouring ; the countenance sunk, and of a pale, livid hue ; the conjunctiva pearly, and the pupil contracted ; the abdomen was tumid, but not tense nor very painful ; the milk was abundant, and the lochia scanty, but not much more so than usual at that period after delivery. The tongue was clean, broad, and slimy ; the skin was covered with a clammy, offensive perspiration, and the heat of the trunk was below the natural standard. The urine had been scanty, but passed without difficulty ; the bowels duly evacuated. The odour exhaled from the body was peculiar and very marked. Her mind was collected, but indifferent to everything. She died a few hours afterward—about sixty hours after the first feeling of disease.

Inspection twenty-four hours after death, present Drs. COPLAND and DENNISON, and Mr. CHOLMONDELEY. The thoracic viscera presented no farther disease than congestion of the posterior parts of the lungs, and loss of vital cohesion. The peritoneum was very slightly adherent in parts by means of a film of puriform lymph which covered the membrane throughout the whole surface. This film was thickest on the right side, and over the diaphragm, stomach, liver, and spleen. These viscera, as well as the kidneys, were healthy, excepting that they were more friable and softer than usual, especially the spleen. The omentum was remarkably softened, and was drawn together like a cord in the middle of the abdomen between the convolutions of the intestines. There was not much fluid effused, but it had a livid and whey-like appearance, especially between the convolutions of the bowels, and between the right ovary and cæcum. The peritoneum, when the film of puriform lymph was wiped off, was congested, with dark blood in points or streaks, and much softened, so that it could be torn in parts like to wetted paper. The uterus was of the usual size, for the period which had elapsed from delivery ; and its structure, when divided, appeared natural. The internal surface of the uterus seemed, also, sound in consistence and colour. The veins of the organ were quite healthy. The spermatic and hypogastric veins on both sides were natural, and contained little blood. The right ovary was of a

203. (*d*) Whatever may be the period or mode of its accession, this variety of the disease always pursues a rapid course; and, unless early arrested by energetic means, it almost always tends to general contamination of the fluids and structures, and to death. At its commencement the nervous system of organic life and the blood appear to be suddenly and seriously affected, as shown by the general loss of vascular tone and of sthenic action; by the disturbance of all the vital functions, and relaxation of contractile parts. The earliest symptom is often the remarkable rapidity of the *pulse*, which is also broad, open, soft, or fluent, or small, thready, or irregular, but always very quick and compressible. *Rigours* and chills are generally absent; or if they have been present, they are either slight or of short duration. In the most rapidly fatal cases, or such as occur in crowded or close lying-in wards, they rarely occur; and in these the disease may be *uncomplicated*, or present no prominent lesion or affection, the whole frame participating in the malady, through the medium of the organic nervous and vascular systems; or, if any prominent lesion appear, the peritoneum and other shut cavities most frequently experience it, and present the appearances hereafter to be noticed.

204. *a*. These more *simple states* of this form of the malady may run their fatal course in from twenty hours to two or three days, the earliest symptoms being remarkable frequency and softness of pulse; pain in the epigastrium or extending over the abdomen, with tympanitic or flatulent distention, and tenderness; frequent vomitings, and sometimes purging; a scanty or suppressed state of the urine; a lurid or dusky appearance of the surface, which is covered by a clammy perspiration, and exhales a peculiar and disagreeable odour; a pallid, apathetic, and sometimes slightly livid or sallow countenance, the eyes being sunk, or surrounded by a dark circle; a broad, flabby, tremulous tongue, which is covered by a slimy or cream-like mucus; little or no thirst; an abundant secretion of milk, and a copious discharge of the lochia, which often becomes offensive or otherwise changed, and great apathy and disregard of the infant and of all relatives. These symptoms may exist in the most marked degree; the respiration becoming short, spurious, and gasping, the vomitings being more frequent, and attended by belchings of flatus, or passing into a pumping up, or eructations of the contents of the stomach, and alternating with singultus or

with leipothymia, and the abdomen still continuing remarkably distended by flatus, until, after a period varying in duration, as just stated, dissolution takes place, preceded either by extreme restlessness, difficulty of breathing, and lividity of countenance, or by sudden or gradual sinking of all the vital functions, and a feeling of impending death. In these cases the mind may evince no farther disturbance than the state of indifference just mentioned, or a low wandering delirium at times, the patient answering correctly when roused, and expressing a conviction of dying, and indifference as to the issue.

205. *β*. When this most malignant form of the disease is *complicated*, or accompanied with any of the prominent lesions to which frequent allusion has been made, the symptoms are somewhat modified either early or in the course of the malady. The most frequent complication is that with effusion into and other lesions of the *peritoneum*. When this surface is prominently affected, the pain and tympanitic distention and tenderness of the abdomen are most severe, and is either general, or is felt most severely near the epigastrium, or in one or both sides of the hypogastrium, indicating in this latter case the origin of the mischief in the tubes or ligaments. In rare and most severe cases, especially if the malady has followed floodings, dissolution may take place before the peritoneum experiences farther change than is presented by other parts; but more generally, or if the case continues two or three days, the abdominal pain subsides more or less, and with it the tympanitic distention and tenderness partially diminish. The abdomen now furnishes indications of more or less effusion into the peritoneal cavity, which generally increases, and which, by its acridity, increases the loss of cohesion which this membrane evinces after death. In other respects the symptoms of this state of the disease pursue the same course as that just described (§ 204), varying only slightly with the severity of attack, and the extent of contamination or change of the circulating fluids and the degree of vital resistance opposed to these and other alterations.

206. *γ*. There can be no doubt of the *uterus* and its *appendages* undergoing, in some cases and on some occasions in which this form of the malady appears, more or less prominent changes; but it is very difficult to determine the period of the disease in which they occur, or the exact procession of the morbid phenomena. Although the peritoneum may present the chief lesions, as shown above in some cases, it is seldom that the uterus, and its appendages especially, are much disorganized without this membrane being also implicated very extensively or throughout. It is very probable that disease may have extended from the internal surface of the uterus and Fallopian tubes to the fimbriated extremities, and thence over the peritoneum, at least in some cases; and that the uterus may have been so early softened and otherwise affected as to implicate the peritoneum, the change thus induced in this membrane rapidly extending, owing to the infected and contaminated state of the frame. It may not unreasonably be assumed that the general infection produced by the exciting cause will render the lochia more acid or septic than in

brownish colour, and slightly enlarged. When divided, a little colourless fluid escaped from the interstices of its structure. The right Fallopian tube appeared slightly inflamed, especially at its fimbriated extremity. No purulent or other matter was found in the sinuses or veins of the uterus. The site of the placenta was somewhat darker than usual at the surfaces, and covered with a dark, semifluid lymph; but the vessels proceeding from the part were empty, and of natural appearance. The veins of the heart were much engorged with black blood. The left ventricle was empty and flaccid, the right was filled with black blood. The body was but little rigid, and the external surface slightly discoloured, of a yellowish livid hue. The whole intestinal canal was greatly distended by gas. This and other cases which I have examined have suggested the belief that in some instances at least the disease extends from the internal surface of the uterus along the Fallopian tubes to their fimbriated extremities, and thence to the peritoneum. I have frequently observed that the structural changes, both in the ovaria and peritoneum, have been greater in the same side as that in which the fimbriated extremities of the tubes were most altered.

more favourable circumstances, and that this state of the discharge, especially when retained in the sexual passages, may contaminate these parts, and give rise to the changes observed, in some cases not only in them, but also in the peritoneum and adjoining cellular tissue. I have usually observed that in these instances the milk has been undiminished, and the lochia more or less offensive, usually abundant, sometimes remarkably putrid or fetid. In this complication of the malignant state of the disease, pain, tenderness, and fulness have commenced either in the hypogastrium, or in one or both sides of this region, and extended to the sacrum and loins, shooting irregularly through the abdomen, which has also presented considerable flatulent distention, with borborygni. The pain has also often extended to the groins and tops of the thighs. In all other respects the symptoms are the same as are observed in the simple and peritoneal states of the malady; but their progress to a fatal issue, although not the less certain, when they are not judiciously interfered with, is generally less rapid, and is often accompanied, as in the former states of the malignant form, with frequent recurrences of faintness or sinking, with dysuria or suppression of urine.

207. *δ*. In the most malignant states of puerperal fever, the *veins* and *lymphatics* rarely present inflammatory changes. It is chiefly in the synchoid form, or when the disease displays a less degree of malignancy and pursues a less rapid course (§ 189, *et seq.*), that purulent matter and other changes are found in these vessels. It does not, however, follow that morbid matters are not imbibed by either the veins or lymphatics, or even by both, and carried into the circulation because they do not evince any lesion of their parietes; on the contrary, it is not improbable that sanious or putrid matters may be imbibed by the veins in this form of the malady, and contaminate the blood, without producing sthenically inflammatory lesions, or any very evident changes, in these vessels; the irritation produced by such matters on their internal surface giving rise, in the existing state of the frame, to an ichorous exudation, which is carried into the blood and mixes with it, and not to that form of lymph which coagulates and arrests the progress of the mischief, nor even to a puriform matter, such as often is met with in the synchoid or less malignant forms of the malady, not only in the veins, but also sometimes in the lymphatics.

208. The *lymphatics* of the uterus and its appendages, and their vicinity, present changes in a few cases which have been viewed as, and which probably are, inflammatory. These changes, however, consist chiefly of the presence of pus in the lymphatics, and of congestion of the glands in the vicinity, and are found chiefly connected with inflammatory changes, or with the presence of pus in the veins, or with purulent deposits, or with ulcerations in the pelvic viscera and parietes. The *symptoms* of changes in the lymphatics of the pelvis are hardly to be recognised during life, owing to their associations with the alterations of other parts just mentioned. I have observed these changes chiefly in cases which have commenced with asthenic inflammatory symptoms referable to the uterus and other pelvic viscera, and even also

to the pelvic parietes, which have been of several days' duration, from eight or nine to fourteen or more, and which have terminated in one or other of the consecutive lesions already noticed (§ 196). I have, however, remarked that these cases generally are attended by acute pain in one or both sides of the hypogastrium, extending to the groins, with tenderness, and sometimes with enlargement of the deeper-seated glands in the groins; but the former of these symptoms also accompany prominent affection of the ovaria and ligaments.\*

209. *D. Of certain Symptoms marking the Form and Terminations of the Disease.*—*Rigours* and *chills* have been stated by most writers as ushering in the disease. This is the case certainly in the more inflammatory states, whether of a sthenic or asthenic diathesis, but they seldom occur in the most malignant forms. When they do occur, then generally are the *milk* and *lochia* diminished or suppressed, if, indeed, the secretion of milk has commenced before the accession of the malady. But in some cases rigours are experienced without the suppression either of the secretion or of the discharge; but this is rather the exception than the rule. In the malignant states of the malady, even when effusion into the peritoneal cavity is very great, neither is the milk, nor is the lochia suppressed or even diminished, but, on the contrary, they are more than usually abundant, while the latter is often very offensive and contaminating. In the more strictly inflammatory, and in the synchoid or intermediate forms of puerperal fever, suppression or diminution of the milk and lochia generally obtains—suppression in the more inflammatory, and diminution in the synchoid. In the malignant states of the disease observed by me in 1823, 1824, and 1825, the lochia was rarely remarked; but in 1827 and 1828, after better ventilation was established, diminution and occasionally suppression of the lochia were observed; the disease having then assumed the synchoid or intermediate grade of impaired vital power. M. DUGÈS states (*Journ. Hebdom. de Méd.*, t. i., p. 348), that in eighty-nine cases observed by him at the Maternité, there were twenty-five instances of suppression or diminution of the lochia during the rigour, twenty-seven of suppression or diminution in the progress of the disease, and thirty-seven instances in which there was no diminution, but were sometimes an augmentation of the discharge.

\* Professor AUSTIN FLINT, of Buffalo, maintains (*New York Journal of Medicine*) the following two prominent propositions in relation to the epidemic puerperal fever which prevailed in that city in 1844: 1. That the disease is an essential fever, and not a merely modified form of peritonitis or metritis; and, 2. That it is a fever having a close analogy with that of erysipelas. In corroboration of the latter, the author narrates the following case: Two ladies were in constant attendance upon a friend who died of puerperal fever. In the course of three days they were both taken ill, one with severe erysipelas, the other with premonitory symptoms of the same disease, and which were fortunately dissipated by the action of an emetic. A labouring woman who was employed to wash the clothes of the same patient, having received a slight scratch on the hand while so doing, was attacked with erysipelous inflammation of the absorbents, and died after a short illness.

M. COLOMBAT D'ISÈRE speaks of puerperal fever under two forms, that of puerperal peritonitis and uterine phlebitis; and in the treatment of both forms, both he and his translator, Professor MEIGS, lay great stress upon the inflammatory origin, and consequently strongly recommend both general and local blood-letting.]

210. In some cases in which the lochia is diminished, an increase of it takes place after a judicious treatment. But a return of the lochia is not always followed by amendment; and when this result ensues, the return of the lochia is evidently the consequence of the amendment, and not the cause of it. In estimating the value of this indication, the time which has elapsed from delivery, and the state of this discharge from the period of delivery, should be considered. It may be stated, as a corollary, that the state of the lochia varies in different epidemics and forms of the malady, and in different individuals even in the same epidemic or endemic prevalence of it, according to its more or less inflammatory character, and to the kind of complication which marks its commencement or progress.

211. (*b*) The secretion of milk, if established before the attack of the most malignant states of the disease, is generally not influenced thereby; and if the accession of the malady precede the appearance of the milk, the accession of this secretion may occur in the course of the malady. I have seen the breasts full of milk at the period of dissolution, although they appeared more or less flaccid. In all respects, this secretion generally presents the same relations to the forms and states of the fever as have been just stated in respect of the lochia.

212. (*c*) A correct interpretation of the pulse is of the utmost importance in the estimation of the nature, forms, and states of this malady; and is not less so as regards the diagnosis and prognosis. A very frequent pulse—a pulse above 110 after parturition, should always be viewed with suspicion, if the acceleration cannot be accounted for, or referred to mental emotion or physical excitement, although no other symptom be complained of; and inquiries, as well as a more particular examination, should be directed to the secretions and excretions, to the condition of the uterus, and to the sensations excited by an examination of the abdomen and hypogastrium. If, in connexion with great acceleration, the pulse is open, expansive, and soft, the inquiries now suggested are the more necessary, especially if pain, fullness, tenderness, or distention in any part of the abdomen be also present. If the pulse rise above 120, the probability of the accession of puerperal fever is much greater, the type or character of the fever being indicated by the tone or resistance furnished by the vessel, and by the various existing symptoms. In the more malignant states of the malady the pulse becomes remarkably frequent, often so as hardly to be counted, and at the same time open, expansive, soft, or fluent, as if insufficiently filled with blood. There are also observed, in connexion with this pulse, a free and offensive perspiration, copious discharges from the bowels and from the stomach, while both the milk and lochia are abundant. These evacuations must necessarily soon leave the vascular system more or less deficient in its contents; and this deficiency must be the more serious, the greater the loss of blood during parturition, and the lower the patient is kept during the first days after delivery, as too frequently directed by accoucheurs, who are more capable of adopting a fashion or mode than of thinking rationally, uninfluenced by hypothesis, and

conformably with the dictates of sound common sense. If we duly consider the effect which the abundant evacuations observed in the course of the more malignant form of puerperal fever must have in reducing the quantity of blood circulating in the vessels, and view this reduction in connexion with the impaired tone or contractile power of the vascular system generally, the want of due relation between the quantity of the blood and the capacity of the vessels containing it must necessarily appear as no mean cause of the leipothymia, faintings, or sinkings so generally observed, and of the rapid progress of the disease to dissolution, especially when a lowering or depletory treatment is adopted.

213. (*d*) In the more malignant states of puerperal fever vomiting is almost a constant symptom. It is generally present from the commencement, and frequently consists at first of a greenish-yellow ropy fluid, afterward becoming greenish-brown, and lastly nearly black, watery, and turbid. A dark greenish fluid is often ejected from the beginning. At first the vomitings are attended by considerable retchings; but as the disease advances to a fatal issue, the matters are belched up with little or no effort. Vomiting sometimes occurs at the commencement of the disease, then subsides, and is followed by diarrhœa, and afterward recurs in its worst form, the diarrhœa frequently continuing also.

214. (*e*) The states of the bowels and of the evacuations vary considerably in the different forms of puerperal fever. The intestinal irritation, or gastro-enteric disorder, which has been viewed by some writers as a form of the disease, is merely a symptom which is often more or less prominent in all the varieties, but more especially in the most malignant and rapidly fatal, in which depression of vital power, alteration of the blood, and loss of vital cohesion of the tissues are the most manifest phenomena. In the more inflammatory, and in the intermediate or synchooid forms, the stools are at first bilious, feculent, or frothy, sometimes costive, or not relaxed, or irregular; but they are often relaxed and irregular, or offensive as the disease advances. In the more malignant states the evacuations are generally dark-green, greenish-brown; in a few cases almost approaching to black. They are commonly, also, fluid, very copious, occasionally slimy, and usually containing numerous small pieces of soft albuminous flakes mixed with them. They are always extremely offensive. Toward the fatal close of the more malignant cases they are often passed involuntarily.

215. *b. The state and appearances of the blood* vary most remarkably in the different varieties of puerperal fever. In the more inflammatory, particularly when the sthenic diathesis obtains, and the disease presents the characters of peritonitis or hysteritis, the blood does not differ materially from the states of this fluid usually seen in other inflammations of serous or fibrous structures. It is chiefly in the inflammatory form that an opportunity of examining the blood, while the patient is living, is afforded the physician. But I have been called to cases of the malignant form, produced by infection, in which venesection has been practiced, and opportunities have thus been furnished, fatally to the pa-

ulents, of observing the appearances of this fluid in that form during their lives.

216. (a) In the case of a patient who exhibited the first symptoms of *puerperal peritonitis* on the evening of the second day after delivery, the pulse being very quick, hard, and full, the respiration rapid, with heat of skin and thirst, Dr. SIMON found that the blood formed a tolerably firm clot, and was covered by a buffy coat of a line and a half thick, the chemical analysis furnishing very nearly similar results to those about to be adduced from ANDREAL and GAVARRET. These physicians made eight analyses of the blood in four cases, one of *peritoneal fever*, the others of *metro-peritoneal*. Two of the cases terminated fatally, and in these a large quantity of purulent matter was found in the abdominal cavity. The following are the results:

Venesections.		Water.	Solid residue.	Fibrin.	Blood-corpuscles.	Solid residue of serum.
1st case	1	787.2	212.8	5.5	122.8	84.5
2d case	1	822.9	177.1	5.4	88.3	83.4
	2	831.6	168.4	5.3	73.6	89.5
	3	851.0	149.0	3.6	60.5	84.9
3d case	1	786.4	213.6	7.2	117.0	89.4
4th case	1	789.4	210.6	3.8	120.0	86.8
	2	802.7	197.3	4.7	109.5	83.1
	3	813.5	186.2	6.1	100.3	80.1
Healthy blood		790.0	210.0	3.0	127.0	80.0

217. The second case, which proved fatal, revealed puriform effusion into the peritoneal cavity. The fourth case did not manifest symptoms of *metro-peritonitis* until the second bleeding was ordered, this disease having been fully developed on the occasion of the third bleeding, when the quantity of fibrin in the blood was greatest. In cases of *metro-peritonitis* quoted by Dr. DAY, from the analysis of SCHERER, HALLER, BECQUEREL, and RODIER, the blood presented a similar increase of fibrin, and a much greater diminution of blood-corpuscles.

218. (b) In cases of *metro-phlebitis puerperalis*, the clot of the blood drawn from a vein was, according to EBERT, large, and more or less concave. It was covered either with a thin, true buffy coat, or more frequently with a thick and often discoloured stratum of gelatinous substance, forming a false buffy coat. Gelatinous coagula of a similar nature were also frequently seen floating in the serum. The microscope often detects pus in the blood in the course of the disease. In two instances, in which the blood was analyzed by SIMON, in this form of puerperal fever, a nearly similar increase of fibrin and diminution of blood-corpuscles to the above were found. The quantity of albumen and of fat in the blood was much augmented, the former amounting to 103.35 and 112.77, the latter to 3.12 and 4.32.

219. (c) I am not acquainted with any analysis of the blood in the most malignant form of puerperal fever, unless that which Dr. DAY adduces from HELLER, who states that the blood was of a very dark brown colour. The clot was dark, of a loose consistence, and covered by a buffy coat, over which was a delicate membrane, which presented under the microscope a finely granular appearance, and fat vesicles.

The serum was turbid, but after standing for some time became clear; its reaction was alkaline; its specific gravity 1025. The fibrin was 5.16; the blood-corpuscles 77.52. According to BECQUEREL and RODIER, the cholesterine and phosphates are increased.

220. The appearances of the blood in puerperal fever will necessarily vary not only with the form and state of the disease, but also with the period or stage at which it has been taken away. During 1821, 1822, 1823, 1824, and 1825, and even in some following years, when the mischievous writings of ARMSTRONG, and other insufficiently experienced authors, had misled those who trusted to ephemeral and unworthy authority, blood-letting had been resorted to in all cases of this disease to which I was called, some of them having been actually moribund, or even dead before I reached them, in consequence partly of the practice; and on every occasion I was struck by the peculiar faint odour and very dark hue of the blood; by the very soft state of the clot when the blood did separate into crassamentum and serum; by the appearance, which occasionally presented itself, of a mass exactly resembling, in colour and consistence, a common jelly, the colouring matter covering the bottom of the vessel in the form of a precipitate; and by, in some instances, a slight separation only of serum, the large, loose, or gelatinous crassamentum consisting chiefly of this jelly-like matter, the lowest stratum of which contained the black or dark brown precipitate of colouring matter. These appearances of the blood were presented in several cases in the hospital in 1823, and three or four subsequent years, in which cases blood had been taken before I saw the patients. It may be here remarked, that I have seen many cases of this form of the disease in which leeches had been applied to the abdomen; but in nearly all, and especially in those which occurred in the hospital, the blood which flowed from the bites did not coagulate; and great difficulty, amounting almost to an impossibility, of arresting the bleeding from them, was generally observed, owing both to the state of this fluid and to the impaired vital cohesion of the tissues characterizing the advanced stage of the malignant form of this domestic pestilence.

221. V. APPEARANCES AFTER DEATH.—The lesions observed after death from puerperal fevers vary remarkably, according to the type, and form, and complication of the malady; the mode and nature of the infection; and the manner in which the infection appears to have invaded the frame. In the more *inflammatory type*, or in those cases which present much of a *sthenic diathesis*, in which vascular reaction are more developed, and the pulse less frequent and attended with more tone and resistance, the alterations of structure, whether limited to the *uterus* or *appendages*, or to the *peritoneum*, or to all these parts, approach more or less closely to those which are consequent upon primary and uncomplicated inflammations of these structures, and are not materially, if at all different from those described when treating of inflammations of the *uterus*, *ovaria*, and *peritoneum* (§ 80-98).

222. A. In the *asthenic* or more *malignant varieties* of this distemper, the alterations of structure present different characters from those ob-

served in the more sthenic states, or in those cases which are characterized by greater vascular reaction and vital resistance. In the *most malignant* of these (§ 198, *et seq.*), the changes consist chiefly of impaired cohesion of the tissues generally, often with more or less of a turbid serous effusion into the serous cavities, more especially into the peritoneal cavity. I examined several bodies after death from this state of the disease in the years between 1822 and 1830, and during that period, as well as subsequently many others, in which the fever manifested an intermediate grade of intensity between that state and the more sthenic or inflammatory, I made notes at the time of the appearances; and the description of them are derived from these sources.

223. *a.* It was but rarely that death took place previously to the effusion of fluid into the *peritoneal cavity*. Such an occurrence, however, was sometimes observed in the most malignant form of the malady, especially when the powers of life rapidly sunk, and the patient expired within thirty-six or forty-eight hours. In these cases the peritoneum was finely ingested or congested throughout, especially its venous capillaries; but the injection was not generally diffused; it was usually in the form of spots, patches, or streaks. Those parts of this membrane which were closely in contact, as if pressed upon, were less vascular. The congested patches were generally of a reddish-brown, or livid hue; and the peritoneum throughout of a dirtier and more unhealthy colour than usual. The membrane was soft, easily torn; and with this loss of cohesion it appeared somewhat thickened. These changes were not limited to a single or to several situations, but were general. In some cases, however, they were most remarkable in the peritoneal coat of the intestines, in others in the *omentum*, which was often contracted, or pushed upward, very much softened, of a reddish-brown colour, and sometimes so readily torn as to be incapable of sustaining much more than its own weight. This diminution of the usual cohesion of the peritoneum was occasionally attended by little or no effusion in the most rapidly fatal cases, or merely by a delicate film of exudation most remarkable in the open interstices between the convolutions of the intestines and viscera. This film of exudation may be unobserved until the finger is passed over the surface, when it will be collected in a sensible semifluid mass. In several of these cases the inspection was made while the body was still warm.

224. In these cases there was but little fluid effusion, not above two or three spoonfuls, and that was of a dirty, light-brown, or reddish-brown hue, or of a whey colour; more rarely it resembled a sanguineous ichor; but it always possessed an offensive odour. In some instances, at least, it may have been the result of *post-mortem* transudation. In cases in which life continued longer to resist the fatal tendency of the malady, or where attempts at reaction had partially taken place, with a nearly similar state of the peritoneum to that now described, there was a greater or less quantity of fluid effused. This fluid, in the more rapidly-fatal instances, and where depression of the powers of life, with flaccidity of the muscles generally, was most remarkable, had a dirty or muddy, or

sero-sanguineous appearance and fetid odour in some cases; and was more abundant in others, and was then either whey-like or of a dirty yellowish tinge. When death had not occurred until about the end of three or four days, the effused fluid was often very abundant, consisting of a curdled substance, of which the more consistent part nearly resembled recently curdled milk, the curd being soft, gelatinous, and friable, of a cream colour, or approaching it; and the serous portion closely resembling a pale whey. This effusion was generally most abundant in the pelvis, in the more depending situations and open spaces between the viscera, and convolutions of the bowels. It is obviously this state of the effusion which induced several French physicians to ascribe the malady to *metastasis* of the milk. In other cases the effusion was equally great, but it presented the appearance of an emulsion of a more or less deep yellow, yellowish-green, or grayish-yellow hue. In some instances it consisted of a dirty serum, with semifluid, albuminous, or puriform matter mixed with the serum. Occasionally the effused liquid was almost puriform, or sero-puriform.

225. *B.* In those cases in which the disease, owing either to the robust constitution of the patient, or to the less intense action or concentration of its exciting cause, has not rapidly sunk the frame into dissolution without some degree of sthenic vascular reaction, the peritoneum, in addition to a large effusion of a serous or whey-like fluid, containing flakes or masses of lymph, or of a puriform or albumino-puriform matter of various sizes floating in it, was very generally covered by a thick coating of lymph, or of a substance of a yellowish or greenish-yellow colour, of a soft consistence, in some places slightly agglutinating the opposing surfaces, in others occasioning no adhesion, however slight, and containing in the open spaces the fluid just described. These exudations were most abundant in the pelvic portion of the cavity and lower abdomen, and sometimes also in the vicinity of the liver, spleen, and diaphragm, and around the omentum, which seldom presented the same appearances in two cases. The odour of this effusion was peculiar and disagreeable, and it, as well as the fluid previously described, was often so acrid as to irritate the backs of the hands of the examiners of the body.

226. *a.* Even in cases of the greatest effusion, the *peritoneum* was often the most devoid of redness; the congested state of its capillaries, particularly of the venous capillaries, noticed in those cases which terminated most speedily and without effusion, was observed only in parts, streaks, dots, or spots, its surface being of a dirty grayish colour. This membrane itself was opaque, thickened, and somewhat softened, and readily torn, more especially in those parts reflected over the viscera of the pelvis and lower abdomen, but sometimes, also, in the iliac fossæ, even more remarkably in the omentum, and occasionally in the mesentery, and in that reflected over the abdominal parietes. In a few instances only were slight ecchymoses under the peritoneum remarked. In rare cases only has gangrene of the peritoneum been observed, and only in those portions reflected over the fundus of the

womb and the appendages, and over the iliac fossæ; and in still rarer instances has it existed in the peritoneal covering of the bowels. In some cases, probably, this change had taken place, or become more marked, after dissolution. The external or adhering surface of the peritoneum, or, rather, the *connecting cellular tissue*, in the most rapidly fatal cases, was sometimes slightly œdematous, or infiltrated by a serous or sanguineo-serous fluid, and this was most frequently seen in the omentum, when it was remarkably softened, and in the Fallopian tubes; but it was associated with no farther change in the uterus, appendages, or veins than slight softening of the former, from participation in the loss of vital cohesion so remarkable throughout the frame. In cases which had continued three or four days, and in which vascular reaction had partially appeared, slight infiltrations of a serous or a sero-sanguineous, or a sero-puriform, or even of a pus-like matter under this membrane were found, occasionally so minute as hardly to be detected, until it was squeezed out upon dividing the parts. When thus slight the peritoneum was opaque, and had a dirty, macerated appearance. These infiltrations were most remarkable under the reflections of the peritoneum over the pelvic viscera and iliac fossæ, and in the omentum and folds of the mesentery.

227. *b.* The *viscera* enveloped by the peritoneum were frequently sound, excepting their impaired vital cohesion, and old or pre-existent lesions, and the changes observed in the *sexual organs and their vessels*, which were the next in importance to those found in the peritoneum. These organs in the most malignant and most rapidly fatal cases, as in those which occurred in the hospital during 1823, 1824, and 1825, generally presented no farther change than remarkable relaxation, flabbiness, or softening, without any purulent matter having been found in the vessels or sinuses of the *uterus*, this organ being but little or not at all contracted, although several days had elapsed from delivery. The peritoneal covering presented the changes just described, in some cases in a great degree, and in those latter the uterine appendages participated very remarkably.

228. These were often the principal changes in the most malignant states, or when the disease at its commencement was not localized in any particular region of the pelvis or abdomen, as in those cases which occurred in the most unfavourable circumstances of deficient ventilation and contamination of the air. But in the less rapidly fatal or intermediate states of the malady, where the duration of the morbid action admitted of the development of various complications, or when the disease appeared to originate in the absorption of morbid matter from the uterus and vagina, or from contamination in these situations, not only were those organs more or less altered, but serious lesions were observed also in remote parts. The *uterus* was generally flabby and relaxed; its substance softened throughout, but most remarkably toward the inner surface, or infiltrated by an ichorous, sero-puriform, or purulent matter; its *sinuses* and *veins* containing also puriform matter, or a substance resembling that found in the uterus, a similar matter irregularly filling or distending the veins and *lymphatics*

not only of the viscus, but also of all its appendages. None of the cases which I examined during 1823 and 1824 presented these changes in the vessels; the first case in which I found the vessels of the uterus and its appendages inflamed or containing purulent matter, occurred in the spring of 1825, Mr. MULLINS having assisted me in the autopsy.

229. The inner surface of the womb was often covered with a gelatinous layer coloured by partially decomposed blood, or by a dark green, or greenish brown exudation of soft lymph, sometimes by a thick purulent coating of a greenish yellow or yellowish brown matter; these matters were generally offensive, or even had become putrid at the earliest period of inspection. The changes in the uterus were always most remarkable in the part where the placenta was attached, whether those seated in the substance of the organ or in the veins and sinuses. The *Fallopian tubes*, *broad ligaments*, and *ovaria* were swollen, injected with blood, infiltrated with an ichorous serum, or with pus; their vessels charged with similar matter, and their substance more or less softened, and readily broken down.

230. *c.* The *veins* and *sinuses* of the uterus are frequently changed, and the *lymphatics* sometimes also implicated, the changes occasionally extending to the whole sexual apparatus and along the spermatic and renal vessels to their trunks. The coats of the vessels, in a few cases, were thickened, the canals partially obliterated, or their parietes contracted in parts and dilated at intervals. The internal surface of the veins was sometimes covered with a false membrane, although it was pale when examined. The adjacent cellular tissue was often infiltrated, or contained purulent or sero-puriform deposits, especially in the iliac fossæ. These changes in the coats and contents of the vessels were in some instances limited to the uterus, in others extended to the appendages; and they occasionally did not exist in the uterus, but were found in the latter parts; and in a few cases they were observed only or chiefly in the spermatic or renal veins. Puriform or other morbid matters were, in a few instances, most abundant in the lymphatics, forming in them small pouches, and more rarely they were found in both the veins and lymphatics. The veins often contained not only ichorous or puriform matter or pus, or these more or less mixed with small, grayish, or light-brown coagula, or with blood variously altered, but generally fluid or grumous, without any marks of inflammation of their parietes.

231. *d.* The *heart* was usually flabby, softened, or friable. In the more malignant cases these changes were often remarkable; and the endocardium was often deeply stained, this change of colour generally extending to the arterial trunks. The cavities of the heart sometimes contained fluid dark blood. A small quantity of a dirty serum, or of a sero-sanguineous fluid, was occasionally effused in the pericardium, especially in the most rapidly fatal states of the malady.

232. *e.* The *diaphragm*, especially at its peritoneal aspect, partook of the changes observed in the peritoneum. Slight infiltrations of sero-puriform or sero-sanguinolent matter were seen in a few instances in the connecting cel-

lular tissue, but they rarely extended into the muscular structure. The *mediastinum* was sometimes infiltrated with a similar matter. The *pleura*, in some of the most malignant cases, presented nearly the same alterations as were found in the peritoneum, more especially the diaphragmatic and pulmonary *pleura*. This membrane was more easily torn than usual, or was softer, or appeared in places cedematous and discoloured, owing to infiltrations of a dirty serum or of a sero-sanguineous fluid in the connecting cellular tissue. The pleural cavities contained, in some cases, a turbid or whey-like serum—more rarely a scanty sero-sanguineous effusion. In some of the most rapidly fatal cases little or no effusion was found, while in some of the more prolonged malignant cases the effusion in, and the state of, the *pleura* were similar to those of the peritoneal cavity (§ 223, *et seq.*), excepting that the quantity of the fluid was much less. In those cases in which the changes were seated chiefly in the uterus and appendages, and in the more prolonged and sthenic form of the disease, the *pleura* presented either slight or no material alteration.

233. *f.* The *lungs* were generally more or less congested with dark fluid blood, especially at their posterior or more depending parts. Their substance was soft and friable in the most malignant states of the malady. In the more prolonged cases, and when uterine phlebitis existed, they sometimes contained small puriform deposits or infiltrations, or larger collections or abscesses, with grayish hepatization or other changes consequent upon congestive pneumonia.

234. *g.* The *digestive canal* presented few changes in its mucous surface. Sometimes, however, inflamed patches were observed; and more or less softening of the mucous membrane, especially of the *stomach*, was not infrequent. Occasionally the softening of this organ was attended by erosions and perforations; and more frequently a brownish, transparent, and gelatinous substance was found between the mucous and muscular coats. Softening and perforation of the *stomach* has been more frequently observed by DUGÈS and others than I have seen them. This physician thinks that the brownish viscid matter exuded from the perforated portion of the *stomach* acts upon the adjoining parts as a caustic, softening, dissolving, and perforating them. But these changes, as they respect the *stomach* and adjoining viscera, are, in my opinion, in a great measure *post mortem*, and are much more rarely observed when the inspection has been made a few hours only after death. The *intestinal parietes* seldom presented other changes than deficient physical cohesion, especially in the most rapidly fatal cases. In a few of longer duration, the glands of Peyer and Brunner were enlarged or otherwise changed; but I rarely observed ulceration of them, or in their vicinity. The whole digestive canal was remarkably distended with air, and contained much brownish or brownish-green fluid matter; that which was found in the *stomach* and *oesophagus* being similar to the matters thrown up shortly before death.

235. *h.* The *liver* was covered by the matter described above as being found in the perito-

neum; and a layer of soft lymph, or of a substance similar to that covering the fundus of the uterus, was often interposed between it and the diaphragm, or between it and the stomach, even, in some instances, where the abdominal portions of the peritoneum were comparatively but little altered. The substance of the organ was often softened, more friable than natural, in some cases congested; in others, pale, soft, as if it were parboiled, and deficient of blood. In rare instances it contained purulent deposits. The *gall-bladder* often contained much greenish bile, which was occasionally thick andropy. The *spleen* was softened, somewhat enlarged, and in the more malignant cases it was so friable and soft as hardly to admit of being handled, even when the examination was made while the body was still warm; and the blood contained in it resembled treacle.

236. *i.* The peritoneal coat of the *kidneys* generally participated in the changes existing in other portions of this membrane. The veins of the kidneys in some instances contained puriform matter mixed with grumous blood; and deposits of pus were found in the substance of the kidney generally on the same side as that in which the ovarium and ligaments were most altered or their veins inflamed. The *brain* and *membranes* were rarely diseased, even in cases attended by delirium. Slight softening was met with in a few instances of the more malignant form of the malady.

237. *k.* Effusions of sero-puriform, or purulent matter in the *joints*, especially the hip, elbow, and knee-joints, and more rarely into the shoulder, ankle, or wrist-joints, were met with in the states of the disease complicated with uterine phlebitis; and when the case was protracted beyond five or six days, infiltration of a sero-puriform or sero-sanguinolent fluid into the cellular and muscular tissues were sometimes observed. These fluids were hardly ever encysted; they always infiltrated, softened, and, as it were, decomposed the texture which they infiltrated, the parts around the softened places gradually passing to a healthy appearance. The muscular structure presented a pale-brown hue where it was thus softened and infiltrated; the skin was lurid or dusky, and the part swollen or boggy, occasionally to the extent of some inches. The soft solids passed rapidly to decomposition; the internal viscera, especially the abdominal, being the first to evince the change. In the more malignant form of the malady this change commenced before the animal warmth had altogether departed. Nearly all my examinations were made before twenty-four hours from dissolution had elapsed, most of them from eight to twelve hours after death. I believe that several of the changes which have been described by some writers have taken place after death, or at least have become more remarkable during the period between this event and inspection of the body, for decomposition follows death more rapidly in this disease than any other.

238. *ii.* *Results of Post-mortem Examinations made by some other Physicians.*—A. M. DUGÈS adduces the results of 341 deaths. In these *peritonitis* was observed 266 times. Of these 266 peritonitic cases the uterus was affected in three cases out of each four. But M. DUGÈS remarks, that if the cases in which pus was found

in the veins, and which he believes, with considerable probability, not to have been cases of uterine phlebitis, be abstracted, the ratio of *metritis* would be very remarkably lowered, and reduced to 29 in 266, or 1 in 9. He states that the *ovaria* are affected in the proportion of one to seven cases; and that in the 266 cases the *stomach* was perforated in 10; the *stomach* and *intestines* were inflamed in 4; there was single or double *pleurisy* in 40; *pericarditis* in 6; *arachnitis* in 1; *purulent deposits* in muscles in 8. It is not improbable, however, as stated above, that the perforation of the *stomach* in some of the cases, at least, was either a post-mortem change, or was increased after death.

239. B. The researches of M. TONNELLÉ are more precise.—(a) Of 222 dissections he found *peritonitis* in 193; alterations of the *uterus* and *appendages* in 197; lesions of both the *uterus* and *peritoneum* in 165; the *peritoneum* alone affected in 28; *uterus* alone in 29.—(b) The alterations of the *uterus* and *appendages* were, simple *metritis*, 79; superficial softening, 29; deep softening, 20; inflammation of the *ovaries*, 58; inflammation of the *ovaries* with abscess, 4=190.—(c) The alterations of the *vessels* were, pus in the veins in 90; pus in the lymphatics in 32; pus in the thoracic duct in 3; suppuration of the lumbar and inguinal glands in 9=134.—(d) The combinations of these lesions were, suppuration of *veins* and *uterus* in 32; suppuration of *veins* and putrescence of *uterus* in 11; suppuration of *veins* with *metritis* and softening in 5; suppuration of *veins* with *peritonitis* alone in 34; suppuration of *veins* alone in 8=90. Suppuration of *lymphatics* and *veins* in 20; suppuration of *lymphatics* and *uterus* in 13; suppuration of *lymphatics* and softening of *uterus*, 6; suppuration of *lymphatics* and simple *peritonitis*, 3; suppuration of *lymphatics* alone, 2=44. Inflammation of *ovaries* with *peritonitis* alone, 29; with various uterine lesions, 27; with *metritis* alone, 8; with softening of *uterus*, 7; with suppuration of *vessels*, 12; with all the preceding lesions, 6=89.—(e) The secondary affections were, in the *pleura*, *pleurisy*, 29; effusion of blood, 6; of serum, 8=43. In the *lungs*, pneumonia, 10; tubercles, 4; abscess, 8; gangrene, 3; pulmonary apoplexy, 2=27. In the *heart*, dilatation, 4; hypertrophy, 3; *pericarditis*, 1; hydro-pericarditis, 6=14. In the *digestive canal*, softening of the *stomach*, 8; perforation of *stomach*, 5; ulceration of *stomach*, 5; gastro-enteritis, 5; entero-colitis, 1=24. In other parts, abscess of the *liver*, 3; of *pancreas*, 2; abscess in muscles, 14; infiltration of blood in muscles, 3; abscess in *pubes*, 2; in the *elbow*, 2; in *knee*, 6; alteration in cellular tissue of *pelvis*, 6; sanguineous infiltration, 2=40.

240. C. Of forty-five dissections made by Dr. R. LEE, the *peritoneum* and its appendages were inflamed in 32; the uterine *veins* in 24; softening of the *uterus* in 10; pus in the *absorbents* in 4. The *peritoneum* was not altered in thirteen cases of the forty-five; and there was no phlebitis in seventeen. Dr. COLLINS found, in thirty-seven dissections, the *peritoneum* more or less affected in all; and in seven fluid was effused in the thoracic cavities similar to that found in the abdomen. The effusion into the peritoneal cavity was of a straw-colour in twelve, and sero-purulent, or of the consistence of thick cream,

in eighteen. It consisted of a sanguinolent serum in seven, and had a glutinous feel when rubbed between the finger and thumb. All these last cases were rapidly fatal, and no coagulated lymph was found in them. In the other cases lymph was deposited in large quantities, and generally, but more especially in the vicinity of the uterus. "The uterus in the great majority was quite natural in appearance; in some it was soft and flabby, and in a few unhealthy matter was found in the sinuses. The ovaries in many instances had suffered much from the effects of inflammation; being generally enlarged, and so softened as to be broken down by the least pressure." (P. 393.)\*

241. VI. PATHOLOGICAL INQUIRIES RESPECTING PUERPERAL FEVERS.—i. Is inflammation or alteration of the blood-vessels, or absorbents of the uterus, a necessary consequence of the passage or imbibition of morbid matters, or of other infecting agents from the sexual passages into the circulation?—Although uterine phlebitis exists chiefly in cases which originate in an extrinsic or intrinsic local infection—which are caused by an internal or external contaminating or infecting agent—and occurs less frequently or more equivocally when the malady is produced by the general infection of the frame received through the medium of the respiratory organs, I nevertheless believe that, in the latter class of cases, more especially if the patient has experienced flooding, or is vitally depressed, or continues under the influence of an impure or infected air, morbid matters or fluids may be imbibed by the uterine vessels, or absorbed from the sexual passages and carried into the circulation to such an extent as to contaminate the circulation and infect the whole frame without producing any inflammatory alterations of the vessels. I was so impressed by the symptoms and course of the disease, and by the examination of the bodies after death, in 1823 and the following years, as to infer at that time, and subsequent experience has confirmed my belief, that morbid matters, or altered or putrid fluids are imbibed, in the circumstances just mentioned, and passed into the circulation, producing the effects now specified without inflaming the vessels, or producing such a change in their internal surface or in their parietes as may be recognised by the unaided senses; and that the passage of these matters from the uterus into the circulation may take place so rapidly and so efficiently as to produce their effects in so malignant a manner, and in so short a time, as not to admit of the production of the usual alterations consequent upon irritation of the vessels along which these matters have passed. From this it may be inferred that the absence of change in the uterine vessels is not a conclusive proof, in rapidly fatal cases of puerperal fever, that morbid matters, or altered fluids, or other infecting agents have not been imbibed from the uterus and carried into the circulation. When the imbibition of such matters or agents takes place without causing, in the first instance, irritation, inflammation, and its consequences in the vessels, there is every reason to believe that the effect upon the frame

[\* It is unnecessary to quote American authorities relative to the pathological appearances found in puerperal fever, as they closely correspond with those described by our author.]

will be the more immediate and intense, owing to the absence of these changes, and to the free passage thus afforded to the morbid agents about to enter into the current of the circulation. Whereas there are equally cogent reasons for concluding that, when the morbid matter excites inflammation of the vessels which imbibe it, the passage of it into the circulation will be either altogether prevented, or retarded, or diminished by the inflammation thereby produced.

242. ii. *Are the uterine vessels actually inflamed in all, or even in the majority of instances, in which they contain pus, puriform, or other morbid matters?*—When the disease is not arrested by the prompt adoption of rational and decided means, or when such means have not been employed early, or not at all, then the altered fluids, an offensive or putrid lochia, or the secretion produced upon the internal surface of the uterus may be imbibed by the vessels, and either inflame them, or contaminate the blood without inflaming them, as inferred above (§ 241), or may both inflame the vessels and contaminate the blood. That the vessels are inflamed, and present the changes consequent upon inflammation, are among the most frequent changes observed in this disease; and that matters similar to those covering the internal surface of the uterus, or in its cavity, are also found in the veins, and that even puriform matter is seen in these vessels, sometimes without any marks of inflammation of the containing vessels, are undisputed facts, and serve to confirm the view, already stated, that these matters may pass into the circulation and change the blood without leaving any signs of phlebitis. It is not improbable that, when the passage of morbid matters from the cavity of the uterus into the veins takes place towards the close of life, or when it has been increased at this period of the malady, the change of the blood remaining in these vessels will then be more manifest; and the contents of the vessels will more closely resemble the morbid matters existing in the uterus, or will be more or less altered, owing to admixture of these matters with the blood; and that, while the matters found in the vessels will thus be much altered, the state of vital power and vascular action at this period of the malady will preclude the occurrence of inflammatory changes in the vessels by which these matters were imbibed. It may, therefore, be concluded, 1st. That the morbid matters found in the uterine vessels may be the products of inflammation of these vessels, and in this case inflammatory appearances or changes are also found in the coats of the vessels. 2d. That they may have been imbibed from the uterus, and their presence may have caused irritation and inflammatory alterations in the vessels; and, 3d. That they may be imbibed by the vessels, pass through them, or be retained in them, especially at an advanced period of the disease, or near the close of life, and yet fail of producing any marks of phlebitis, although contaminating the blood and all the frame.

243. iii. *Are the softening and other changes often found in the substance of the uterus and of its appendages the results of inflammatory action, and to what other pathological conditions may they be imputed?*—(a) Certain of these changes are the undoubted consequences of inflammation,

others are the results of a very different state of vital and vascular action. Even the most obviously inflammatory lesions are not referable to pure sthenic action, but rather to an asthenic or diffusive state, unattended by the exudation of a healthy lymph, and characterized by its tendency to spread, to soften, dissolve, or disorganize the parts which it affects; and to infiltrate them with a sero-puriform or sero-sanguinolent matter. The flabbiness of the parts, their swollen, softened, and infiltrated states, their friable and almost putrescent conditions in some instances, and the deposits of puriform matter, without any cyst or exudation of firm lymph in others, evince the asthenic character of the vascular action, of which these changes are the results. In some cases, especially when vital power is less depressed and the disease is more prolonged, the matter found in the substance of these organs is more consistent, in larger collections, and more nearly approaches that produced by sthenic action.

244. (b) The depression of vital power and contamination of the circulation caused by the exciting or infecting agents, when they operate energetically, occasion changes in the lochia, or so affect the fluids exuded from the internal surface of the uterus and sexual passages as not merely to irritate the parts with which they come or remain in contact, but also to contaminate them locally, so as to partially dissolve their vital cohesion, to soften and almost liquefy or putrify them, even before life has taken its departure. This local contamination thus supervenes upon the general infection produced by the poisonous agent, and in proportion to the intensity of its operation, relatively to the remaining power of vital resistance, will be the extent of change; of softening or disorganization that will result in the uterus, in the ovaria, and in the ligaments, the mischief extending, moreover, to the peritoneum, and spreading throughout its surface with a rapidity proportionate to the reduction of vital power and to the contamination of the circulating fluids. In many of these cases the softening and disorganization of the uterus and appendages, especially of the ovaria, are carried to the utmost extent. If, however, the examination of the body be delayed beyond eighteen hours after death, these changes may be viewed as partly *post mortem*.

245. iv. (a) *Is the peritonitis existing in the majority of cases of puerperal fever a primary morbid condition? (b) or is it consecutive of the infection and febrile action? (c) or is it the result of an extension of the morbid action from the uterus and appendages to this membrane?*—These are questions by no means easy to solve, for they admit of being answered both affirmatively and negatively, inasmuch as there is reason to believe that the procession of changes is different, or even opposite in different cases or forms of the malady, and according to the channels through which the causes invade the frame.—(a) Instances have occurred in which I have believed the disease to originate in inflammation of the peritoneum, of greater or less extent, the accompanying fever preventing varying grades of action between the sthenic diathesis on the one hand, and the asthenic on the other. The peritoneal affection may be primary, and yet appear as a complication, or as a

consecutive lesion, especially when it occurs very soon after labour, or is developed with the reaction following the shock produced by parturition. Indeed, both the fever and the peritoneal affection may be coæteaneously produced; the latter, commencing as reaction, follows the depression caused by delivery, or by the exciting causes of the malady. This latter mode is probably that which actually obtains most frequently, whether the disease is characterized by sthenic or inflammatory action, or by asthenic action, or marked deficiency of vital power. But, as reaction is adynamic and imperfect in the latter cases, the prominent affection of the peritoneum in these is modified accordingly, and presents alterations varying in extent and character, especially as regards the fluid effused, with the intensity or concentration of the cause, with the state of vascular action and vital power, with the constitutional peculiarities of the patient, and with the several circumstances of the case.

246. (b) That the peritoneal affection may, however, be consecutive of the constitutional infection and febrile action, at least in some instances, is shown by the fact that death has taken place, although in comparatively rare cases, before the peritoneum has presented a more remarkable change than other parts—before exudations of lymph or fluid in its cavity had supervened; such cases having occurred in the same ward, and in similar circumstances, with those in which the peritoneal symptoms and effusion into the cavity were most prominent; in some of these cases effusions of fluid have also taken place into the pleural cavities, and even into the pericardium.

247. (c) That the changes in the peritoneum are often an extension of those which had previously taken place in the substance or vessels of the uterus and its appendages cannot be disputed. The phenomena characterizing the progress of the malady; the occasional limitation of these changes to the peritoneum reflected over the pelvic viscera, the uterus and appendages, in some one or more of their constituent structures, being more or less altered; and the frequent extension of the peritoneal changes, as distinctly marked by the symptoms, from the pelvic peritoneum to the reflections of this membrane over the abdominal viscera and diaphragm, demonstrate that the abdominal alterations often commence and advance as now stated. In those cases which originate in a local infection, and even in those where the general infection is followed by a local contamination, it may be reasonably inferred that the morbid irritation and its consequences, thus produced in the internal surface of the uterus, extend along the sexual passages—along the Fallopian tubes to their fimbriated extremities, and thence to the peritoneum, over which it spreads with a rapidity great in proportion to the intensity of the infection, and to the prostration of vital power and resistance.

248. v. *In what manner are the consecutive changes in the joints, cellular and muscular tissues in the eyes and in the viscera, to be explained?*—These consist chiefly of the deposit of puriform matter, in smaller or larger collections, and of infiltrations of this matter in the softened, disorganized, or otherwise altered structure; and are only sometimes observed. That

they are to be referred to the imbibition or absorption of puriform, or ichorous, or putrid matters from the uterus into the circulation, or to the passage of a purulent or ichorous fluid into the blood from irritation or inflammation extending from the sinuses and capillary veins of the uterus and appendages, is generally admitted; either modes of contamination, or both, occurring according to the early states and peculiarities of the case. The morbid matter, having thus passed into the blood, excites and develops a diffusive form of inflammation, with puriform deposits, softening and disorganization of those parts which are most predisposed by previous disorders, by depressing influence, or by impaired vital resistance. These consecutive or secondary purulent collections and destruction of parts have been viewed by some as resulting from the mere deposit of the morbid matter circulating in the blood; while others more correctly consider it as the termination of an asthenic, gangrenous, or destructive form of inflammation produced by the presence of the imbibed contaminating matter in the circulation. This matter, by acting upon the interior surface of the capillaries, produces effects much more disorganizing and diffusive than those resulting from the usual states of inflammation consequent upon external irritation. Although these secondary lesions are most frequently seen after puerperal fevers, and uterine phlebitis occurring in the puerperal state, they supervene in various other circumstances; and as I shall show in the article *UTERUS*, sometimes upon ulceration of the *os uteri*, and of other parts. This subject is more fully discussed in the articles *ABSCESS* (§ 24, *et seq.*), *ABSORPTION* (§ 15, *et seq.*), *CELLULAR TISSUE* (§ 10, *et seq.*).

249. VII. *DIAGNOSIS.*—After what has been remarked respecting the forms and states of puerperal fever, and the descriptions of these forms and of the appearances after death, it is unnecessary to do more than briefly to notice this topic. The *diagnosis* of fevers in the puerperal state has, however, been very loosely stated by some writers, and most inaccurately by others; while by nearly all those who have written, with a dogmatism and self-sufficiency which would be ridiculous if they were not most mischievous, and actually destructive of life in the most interesting epoch of female existence, the inflammatory form has been assumed as the type of all the others. Most writers, even the most recent, have described and attempted the diagnosis of puerperal fevers with reference only to the local or prominent affections presented at their commencement or their course, and with entire neglect of the different states of vital power and resistance which characterize their several forms, more especially the synchoid and malignant. The vital depression, the poisonous contamination, the mental apathy, or, rather, the despondency conjoined with indifference, characterizing the worst cases from their commencement, and the origin of such cases in infectious causes—in foul air, poisonous effluvia, contagious emanations, &c., even of a domestic nature, and which I have fully described at another place (*see PESTILENCE, preservation from*, § 10, *et seq.*)—heightened, favoured, or predisposed to, by the exhaustion consequent upon parturition,

and the state of almost inanition, or of deprivation of requisite nourishment and even of accustomed stimuli in which puerperal females are often kept too strictly or for too long a period—are pathological conditions and etiological circumstances of the greatest importance not only as respects the diagnosis, but even more as regards the indications and the means of cure.

250. *A. The inflammatory form of the disease, occurring either as peritoneal, or metro-peritoneal, puerperal fever, are indicated by the mode of accession, by the seat of pain and tenderness, by the vascular reaction consequent upon shivering, by the state of the pulse, especially its hardness in the former and its fulness and firmness in the latter; by marked diminution or suppression of the milk and of the lochia; by thirst and dryness of the mouth and tongue; by the often costive state of the bowels at the commencement, and by irregularity afterward, the evacuations being offensive; and by scanty urine, the excretion of it being more or less disordered. Peritonitis, occurring in the puerperal state, presents most of the symptoms described when treating of inflammations of the PERITONEUM, the disease assuming more or less of a sthenic form on the one hand, or of an asthenic on the other, according as the disease is inflammatory, synchoid, or malignant, the symptoms and lesions found after death very closely approaching, or being identical with, those described under that head, the chief differences arising from the constitutional influence exerted by the puerperal state, by the constitutional infection, or by the exhaustion, or inanition, or other circumstances of the patient.—(a) Peritoneal puerperal fever cannot be confounded with *gastro-enteric irritation* (§ 103, *et seq.*), if the abdomen be carefully examined; for in this latter the abdomen is not tympanitic, nor tense, nor very tender on pressure; nor does it usually appear so soon after delivery, nor cause so marked constitutional disturbance as the peritoneal or metro-peritoneal disease.—(b) *Ephemeral fever* cannot be mistaken for any state of inflammatory or synchoid puerperal fever, inasmuch as the former is unattended by the severe abdominal pain, tympanitic distention and tenderness characterizing the latter; and is, moreover, a much less severe disease, of much shorter duration, soon terminating in a copious perspiration, the lochia being uninterrupted, and the breasts continuing distended.*

251. *B. Puerperal fever, commencing either as hysteritis or as ovaritis, or affecting chiefly the ligaments, and either limited to these, or extending thence, to a greater or less extent, over the peritonum, whether it assumes an inflammatory or sthenic type, or a synchoid or asthenic, will generally be recognised by the severity of the constitutional symptoms; by the persistence of the local signs, especially the pain, tenderness, fulness, and tension in the hypogastric and iliac regions, shooting through the abdomen to the loins and tops of the thighs; by the rapidity of the pulse, prostration of strength; by the dysuria and irregularity of the bowels; and by the diminution, irregularity, and offensive state of the lochia. If the peritonum continue unaffected, the abdomen will be neither tympanitic, nor tense, nor ten-*

*der; excepting towards the pelvic regions, where the pain, tenderness, and fulness will be considerable, and the uterus will generally be felt hard and enlarged. The persistence and duration of these symptoms, the grave character of the attendant fever, the disordered states of the secretions and discharges, will distinguish these states of puerperal fever from after-pains, from ephemeral fever, and from gastro-intestinal irritation.*

252. *C. The malignant form of puerperal fever often arises from similar infectious and contaminating sources to those which produce putro-adyamic fever; and it may be considered in every respect a putro-adyamic fever in the puerperal state, presenting all the characters of this fever in an aggravated form. It is distinguished chiefly by the absence of chills or rigours at its accession, by a remarkably rapid, soft, broad, open, and compressible pulse, which soon becomes small, weak, fluent, and irregular; by a broad, flabby, or tremulous tongue, covered by a slimy or cream-like mucus; by the little, or almost entire absence of thirst; by the character of the discharges from the stomach and bowels, as above described (§ 214); by the persistence of the milk and lochia, or the greater abundance and more putrid state of the latter; by the dusky, lurid, or sallow appearance of the general surface and countenance; by the free, clammy, and peculiarly offensive perspiration; by the frequent recurrence of faintness or of a sense of sinking, with moral apathy and vital depression; by the manifest contamination of the circulating fluids and impaired vital cohesion of the tissues; by the quick and peculiar state of perspiration; by the extremely tympanitic distention of the abdomen, and the almost constantly rapid progress of the malady to dissolution, if not early arrested by judicious means; singultus, eructations of flatus, and dark fluids from the stomach, a dirty livid hue of the face and general surface, and loss of the power of and control over the sphincters, ushering in death. After death, the rapid accession of putridity, especially of internal organs, the pelvic particularly, and the little or no diminution of bulk—the almost entire absence of emaciation, notwithstanding the free discharges from the stomach, bowels, and skin during the disease, remarkably attract attention.*

253. The malignant form of puerperal fever has been considered by many, especially when the peritonum is prominently affected, as an *erysipelas* of internal surfaces and organs in the puerperal state; and by others as *typhus* or *typhoid fever*, modified by this state.—(a) The evidence adduced above (§ 151, *et seq.*), and the facts which have fallen under my own observation as early as 1826 and 1827, have convinced me of a connexion between *erysipelatos* and *puerperal fevers*, arising chiefly out of a similarity, if not identity, of their respective predisposing and exciting causes, and of the constitutional—nervous and vascular—conditions existing in their progress, and characterizing their terminations; the connexion being remarkable chiefly as respects the synchoid or intermediate states of puerperal fever, more especially that with prominent affection of the peritonum. It cannot be said that both maladies are identical, for their respective seats are altogether

er different. The connexion or similarity I now point out certainly obtains in a remarkable manner, and is of great importance as respects both the origin and treatment of puerperal fevers. A similar connexion may, however, be traced between several other malignant maladies, arising out of their exciting causes, and their prominent pathological conditions, tendencies, and terminations. A septic or contaminating animal poison, varying in kind, administration, application, and avenue of invasion, is the exciting cause of them all; and, while this cause depresses organic nervous power, contaminates the circulating fluids, loosens the vital cohesion of the tissues, weakens constitutional or vital resistance, and disposes the whole frame to dissolution, it thereby generates miasms, exhalations, and secretions, equally poisonous with itself, and produces effects altogether similar to, if not identical with, those which itself had produced. In this category of effects may be arranged the severer forms of erysipelas, diffusive inflammations of the cellular tissue, poisoned wounds in dissection—the necroscopic poison—puerperal fevers, especially the synchoid and malignant, putro-adyamic fever, and other fevers of a malignant form, which are generally produced by animal emanations or poisons.

254. (b) The opinion as to puerperal fevers being prevailing *typhoid* or *other fevers*, occurring in the puerperal state, may be thus disposed of: 1st. The most malignant form of puerperal fever does not produce typhus or typhoid fevers in other persons, however susceptible they may be, by age and otherwise, of the infection of these fevers, as shown on several occasions both in lying-in institutions and in private practice. 2d. When other fevers, both typhous and exanthematous, occur in the puerperal state, whether the invasion of such fevers have taken place immediately before or very soon after parturition, these diseases retain their distinctive characters, although they are generally much more severe in the puerperal state, as I have observed on various occasions. As respects the exanthemata, the diagnosis requires no remark; but in respect of typhus fever appearing after delivery, a few observations may be here offered.

255. (c) *Typhus* or *typhoid* fever may appear after delivery, from infection either shortly before or soon after this event. And it is not improbable that an adynamic or typhoid fever may occur in the puerperal state, owing to great anxiety of mind, or other moral emotions, or to exposure to various morbid exhalations. When, however, typhoid or adynamic fever occurs during child-bed, it generally assumes a more than usually severe and almost malignant form. The patient complains, after chills or rigours, of severe pain of the head, back, and lower extremities; rapid pulse; dry, hot, and acrid skin; wandering or low delirium, occurring first at night, and becoming permanent, the ideas running upon one subject; deafness, and suffusion of the conjunctivæ; grinding of the teeth, thirst, and dryness of the mouth, the tongue being loaded, brown, or furred, dark, and dry. The position of the patient is on the back, with the knees but little or not at all drawn up. During the delirium the patient gives short and irrational answers when roused. The coun-

tenance is sunk, livid, or sallow; the features are afterward sharpened; and the delirium passes into coma, with subsultus tendinum. The pulse varies from 100 to 120 or 130, and is generally soft and quick; respiration is quick, and accompanied with frequent sighing; the abdomen is not remarkably, or but slightly, tumid or tender; the bowels at first are slow or costive, subsequently irregular or relaxed, the stools being offensive; the urine is scanty and turbid, sometimes suppressed; and the milk and lochia are early diminished, and soon afterward entirely suppressed. At last the patient sinks down in bed; the tongue is dry and dark; the evacuations are involuntary, and without consciousness; and eschars form on the parts most pressed upon. The duration of the fever is generally longer than that of any of the forms of puerperal fever, and is seldom shorter than fourteen days, and is sometimes above twenty-one days. The history of typhoid fever in the puerperal state shows several points of difference from puerperal fevers; indeed, the phenomena just described are distinctions between these fevers, most of them not existing in the latter; and, in addition to these, petechiæ are observed in typhoid, and the measly eruption in true typhus, these never appearing in any of the forms of puerperal fever.

256. VIII. PROGNOSIS.—An opinion of the result of a case of puerperal fever should depend chiefly on the form and state of the disease, in respect both of the character of the constitutional disturbance and the prominent local affection, and on the period of its progress, and the effect produced by treatment.—a. In the *inflammatory form* of the malady, a *favourable issue* may be anticipated from a gradual abatement of the acute symptoms; from a return, or an increase, or a more natural state of the secretions and excretions; from a diminution of the pain, distention, tenderness, and tension of the abdomen; and from a less frequent and more natural state of the pulse. An *unfavourable result* is indicated by the appearance of delirium; of increased distention of the abdomen, which becomes round and very prominent; by an aphthous eruption in the throat; by increased frequency and irregularity of the pulse; by a sudden cessation of pain; or by evidence, by percussion, of copious effusion into the peritoneal cavity; by sinking and sharpening of the features; by continued eructations of flatus with dark fluid matters from the stomach, and singultus; by rapid or gasping respiration; by cold, clammy perspiration, or a similar state of the extremities; by involuntary evacuations and restlessness; these latter phenomena indicating speedy dissolution.

257. b. The *synchoid* or *intermediate grades* of puerperal fever furnish nearly similar phenomena to the above, by which their terminations may be anticipated; for, although the sthenic diathesis obtains at the commencement, or during the early progress of the inflammatory form, still it more and more nearly approaches the synchoid or asthenic, as respects both the constitutional disturbance and the local changes, as the disease continues, especially as it proceeds towards an unfavourable issue, so that an advanced stage of the inflammation differs but little from the same period of the synchoid form, as respects the indica-

tions of the ultimate result. In this latter form of the malady treatment is seldom availing, unless it be early and decidedly prescribed; and unless symptoms of amendment, or, at least, of alleviation, soon follow the remedies employed. If the secretions and discharges have been suppressed, the return of these; an improvement in the states of the pulse and of the abdomen, as ascertained by a careful examination; and the capability of turning or of lying for a time on either side, are the chief indications of a *favourable issue*; and these may not continue long, an exacerbation of all the symptoms sometimes occurring, and soon carrying off the patient; or an alleviation of the more painful symptoms may take place, the pulse still continuing rapid, and after a very few days be followed by secondary affections, as described when treating of the metro-phlebitic state of the malady, which ultimately destroy the patient.

258. An *unfavourable issue* is indicated by the symptoms already mentioned (§ 256), and especially by the character of the vomitings and of the matters thrown up; by singultus and the state of the respiration; by faintness or leipthymia; by failure or irregularity of the pulse; by the amount of effusion in the abdomen, as indicated on percussion, and by the toleration of percussion in connexion with effusion; by the suppression of urine; by the indifference of the patient to her child, and to all other objects; and by an early entertained idea or anticipation of an unfavourable result by the patient herself. Sinking of the animal heat and of the features, and a lurid hue or lividity of the face, extremities, or surface generally, indicate approaching dissolution.

259. *c.* The *malignant form* of the malady often manifests the result from the accession of the attack, especially in the suddenness and severity of the appearance of the abdominal symptoms. This form of the disease is seldom recovered from, if it continue but a few hours, without the administration of appropriate and energetic means; and, unless these soon procure an alleviation of the symptoms, especially of the vomitings, and of the pain and distention of the abdomen, and an improvement in the pulse, particularly in diminishing its frequency and in improving its tone, hopes of recovery should not be entertained. The symptoms just enumerated usually precede a fatal issue; and that issue may be expected if the lurid, dark, or nearly livid hue of the countenance and surface; the clammy and peculiarly offensive state of the perspiration; the putrid odour of the lochia; the moral apathy, and mental and physical depression appear soon after the attack; inasmuch as these symptoms indicate a contamination of the circulating fluids, and a depression of organic nervous energy which is rarely removed. A soft or flabby state of the tissues in conjunction with the gastric symptoms described above; a pulse too fast to be accurately counted; loss of power over the sphincters; absence of abdominal pain, the abdomen continuing tumid, with a swagging or tremulous motion when struck or examined, loss of pulse and coldness of the extremities are rapidly followed by death.\*

260. IX. PATHOLOGICAL INFERENCES. — (a) *Puerperal fevers* are varied in the character or type of the constitutional disturbance, and in the seat or seats of the prominent local changes. — (b) They present the most inflammatory and the most malignant forms—the most sthenic, or the most asthenic or ataxic, with all intermediate grades, according to the nature of the exciting causes, and the mode of operation or avenue of invasion of these causes—as the local affection is primary or consecutive, and as the constitutional disturbance, with its secondary changes, are the effects of infection by an animal miasm or poison. — (c) Owing to these varied constitutional conditions; to these different grades of vital power and resistance, and

one was attacked before delivery; one in six hours after delivery; one in nine hours; one in ten; three in twelve; one in thirteen; one in fifteen; two in seventeen; one in eighteen; one in twenty; one in twenty-one hours; and two in thirty hours. Thirty-two were attacked on the first day; twenty-nine on the second day; eight on the third; two on the fourth; and one on the eighth day. The attacks were earlier than those observed by me in Queen Charlotte's Lying-in Hospital in 1823, and the seven following years. During that period the majority of the cases were of the most malignant type, and the largest proportion of the attacks were on the second, third, and fourth days. In one most rapidly fatal case the attack was on the fifteenth day from delivery. The statement of Dr. COLLINS, that in only thirty-three cases out of eighty-eight was the accession of the malady attended by shivering, very nearly agrees with my own experience, which also is in accordance with the following: In fifty-six deaths this termination took place at these periods from the attack, viz.: Two in twenty-four hours; one in twenty-seven; one in thirty-six hours; nine on the second day; fifteen on the third day; thirteen on the fourth; four on the fifth; four on the sixth; three on the seventh; two on the eighth; and one on the eleventh day. "Forty-four of the eighty-eight cases occurred in women who had given birth to first children; sixteen with second children; nine with third; six with fourth; seven with fifth; two with seventh; and four with eighth children. Thirty of the forty-four women delivered of first children died. Fifty-four of the eighty-eight gave birth to male children." Dr. COLLINS adds, that "when he was assistant physician in 1823, puerperal fever raged to an alarming extent. The master (physician) of the hospital was a strong advocate for the free removal of blood generally at the commencement of the attack. With his approbation it was resorted to with great frequency, and in the promptest manner. The effect on the patient and the mortality was such as to satisfy him fully of the inexpediency of adopting this line of treatment." It may be remarked in palliation of such adoption, that just before this outbreak of the fever several works had appeared filled with the results of an experience of a few months' duration of this malady, most of them written before the authors were of legal—certainly not of medical age, although distinguished by the title of doctor; which results were dogmatically, and, to my own knowledge of one of these productions, falsely adduced in favour of blood-letting. In the case of this malady, as in that of a somewhat similar pestilence, blood-letting was once extolled as the "sheet anchor" of treatment, especially by the navy wielders of the lancet, who, like DOVER of old, rendered this minute instrument of mighty mischief one of the greatest importance with those who credulously received assertions as facts, and believed all assertions according to the confidence with which they were made. Early in the present century a work appeared on the diseases of intertropical countries, in which blood-letting was the first "sheet anchor," and calomel was the second. In it all preceding writers were ridiculed, and told they knew nothing of what they had written upon, and these remedies were considered so good that patients could hardly have too much of them. This work was the guide of all the inexperienced in tropical diseases, and the results may be inferred from the statement made to me by an inspector of hospitals when I was travelling within the tropics, in answer to my request to know his opinion of the treatment of the fevers of the country, that, for the first nine cases of fever he treated he prescribed blood-letting, relying on the confidently-expressed results of the experience of the author of the work alluded to, and they all died; that he next tried large doses of calomel, but was not more successful; and that he lastly had recourse to cinchona (quina was not then discovered), but he could not get it to remain on the stomach. I suggested to him that he would succeed better if he conjoined the bark with capsicum. He some time afterward was himself a victim to this fever.

\* Dr. COLLINS, formerly the resident physician of the Dublin Lying-in Hospital, states that of eighty-eight cases

diverse complications, the arrangement of the forms of these fevers must necessarily be arbitrary and conventional, inasmuch as each form is not defined by any precise limit or line of demarcation, but passes insensibly into that nearest it in grade or character.—(d) The contaminating or poisonous influences of the causes upon the circulating fluids, and their depressing effects upon organic, nervous, and vital power, affect the states of all the secretions and excretions, and ultimately impair the vital cohesion of the tissues and the tone of the vascular system and of the capillary vessels, thereby occasioning effusions into serous cavities, and increased discharges from exhaling and secreting surfaces, and all the phenomena characterizing the progress of the more malignant forms of this malady.—(e) The most important parts of the pathological conditions of puerperal fever are the states of vital power and of vascular tone characterizing the disease, inasmuch as these states, more than the seat and amount of local lesion, mark the kind and tendency of the malady, and either resist or remarkably favour the extension of the local changes.—(f) According to the mode of operation of the exciting causes, or to the avenue by which these causes invade the frame, either the constitutional infection or the local affection may be primary; but, whichever may be secondary, an aggravation of the primary disorder will be produced by it, the one reacting upon and increasing the other until disorganization and death result, if the procession of morbid actions be not arrested by agents capable of changing the states of vital power and vascular action, and of enabling them to resist farther alterations, as well as to restore those which have already taken place.—(g) A due recognition and estimation of the states of vital power and of vascular action are the basis on which a rational treatment of puerperal fevers should be placed, inasmuch as it is by means of agents affecting these especially that we are enabled to arrest the progress of the malady, and to resist the extension, and even to remove the effects of the local disease.

261. X. TREATMENT.—It is obvious that, in order to be successful, the treatment of puerperal fevers should be appropriately assigned to each of its forms; and that, as these forms are characterized not only by different, or even opposite states of vital power and of vascular action—by very different pathological conditions—so the treatment should be assigned accordingly. Has there appeared in the numerous works on puerperal fevers, or in the still more numerous productions on the diseases of females, either a due estimation of the different forms of these fevers, or a satisfactory exposition of the treatment suited to each form, supposing that the forms and states of these fevers are there duly set forth? Let the reader, who may be supposed to be excited by a desire to know as much as possible of the opinions of those who profess themselves to be experienced by attempting to instruct others—of opinions of the greatest importance to the community respecting, moreover, the most fatal disease known in this country, and that disease attacking only females in the most interesting and most important period of their existence—refer to the works enumerated at the end of this ar-

ticle, and then let him answer not only the above question, but also the following two questions: Have these numerous productions, which have appeared since the latter part of the last century, advanced our knowledge of the pathology and treatment of these fevers in any important particular, or in any way excepting as respects a few subordinate details? Have certain remedial measures, confidently recommended many years ago by physicians possessed of experience, and capable, by ability and education, of observing and of reasoning with, at least, an average degree of accuracy, been satisfactorily tested, or adopted, or at all appropriately employed in those institutions which are most notorious for the generation of these maladies? Leaving these questions to be answered by those whom they may concern, and suppressing those painful and humiliating reflections which the subject suggests to the minds of those even partially informed as to its ethical as well as therapeutical relations, I proceed, *first*, to consider the treatment which my experience has shown me to be most appropriate to the different forms and states of puerperal fever; and, *next*, to notice the several methods and means advised by other writers, and the value which I believe to be attached to them.

262. A. THE INFLAMMATORY FORM OF PUERPERAL FEVER, in its more sthenic manifestations, whether commencing as *puerperal peritonitis*, or *hysteritis*, or as *metro-peritonitis*, requires the prompt and decided antiphlogistic treatment recommended for inflammations of the PERITONEUM (§ 137, *et seq.*) and of the UTERUS, with a due consideration of previous sanguineous losses or exhaustion of the patient, of the state of her constitution, and of the several circumstances and symptoms connected with the case. It should not be overlooked that all cases of these inflammatory states of the disease are not possessed of an equal amount of sthenic diathesis; but that, owing to the nature of the causes, and to the constitution or previous state of the patient, the febrile disturbance as well as the local affection may approach nearer the asthenic than the sthenic condition, and thus the synchoid or intermediate grade of the malady be nearly approached, if not altogether reached. In these states it may be a matter of doubt as to the extent to which vascular depletions, either general or local, ought to be carried; or, if they have been already employed, as to the propriety of repeating them. In these circumstances, and especially in large towns, or in a vitiated atmosphere, less risk will accrue from the rational adoption of other measures; from a due recourse to calomel and opium, conjoined, in the more asthenic cases, with camphor, to terebinthinate embrocations or fomentations, and to the other means recommended for *peritonitis* (see PERITONEUM, § 138–143), than from large or frequent bleedings. When the disease commences in the uterus, in the form either of *hysteritis*, or of *metro-peritonitis*, or in the uterine appendages, as *ovaritis*, too large depletions may only favour the extension of the inflammatory action, unless the *sthenic* diathesis exist, or the patient be not remarkably exhausted by previous losses or inanition. When the local affection assumes an *asthenic* character, the most appropriate treatment is that

which I have advised for the asthenic form of peritonitis. [see art. PERITONEUM, § 150], and which is equally suited to the other prominent affections appearing in this and in the synchoid forms of the malady.

263. *B. THE SYNCHOID OR INTERMEDIATE FORMS OF PUERPERAL FEVER*, however commencing—in whatever organ or structure, as fully set forth (§ 185, *et seq.*)—require a treatment which should have strict reference to the states of vital power and vascular action; to the predominance of either the sthenic or asthenic diathesis; for, however obvious may be the local seat of mischief, the treatment is not materially or at all different as respects the local affection, especially at an early stage, or until the disease is far advanced. In this form of the disease, especially when commencing with rigours, the early reaction associating the local disease assumes more or less of a sthenic or inflammatory character, which, however, soon passes into the asthenic, especially when the patient breathes a close or impure air, or is morally or physically depressed, or when the veins are more especially affected. In many cases of this form vascular action is often attended by great irritation or excitement, and by an expansive or open state of the pulse, indicating an alteration in the state of the blood both in quality and in quantity—in quantity especially as relates to the capacity of the vascular system, and to the power of adjusting itself to the quantity of blood contained—and in these *vascular depletions* are often injurious, whether general or local; and although, in some instances, a small or a local bleeding may be of service, yet, if it at all pass a very moderate amount, the most irreparable mischief may ensue. In this form of the malady, the inflammatory states of the parts so generally complicating it, if not altogether asthenic at the commencement, soon passes into this condition, especially when the treatment is calculated to lower the powers of vital resistance; and, as vascular depletions not merely possess this property, especially with females confined in lying-in wards, or in the close and impure air of large towns, &c., but also remarkably favour the imbibition and absorption of the discharge retained in the uterus and sexual passages, the occurrence of uterine phlebitis or lymphangitis, and contamination of the circulating fluids, they are most liable to be injurious, and they ought to be most cautiously and moderately prescribed.

264. *a.* A large proportion of the cases of this form of puerperal fever originates in imperfect contraction of the uterus, owing to deficiency of vital power, or to the vital depression more immediately following the impression of the infectious or poisonous cause; the imperfect contractions favouring the retention of an unusually large quantity of lochia within the cavity of the organ and in the vagina, followed by changes in this discharge of a septic and contaminating nature. Thus altered, the lochia not merely affects the surfaces with which it is in contact, but is also imbibed by the vessels, inflaming or irritating them, and altering the blood. With the view of enabling the uterus to throw off the coagula and fluid which may be retained in it, I have advised, in cases where the contraction of the organ after delivery ap-

pears to be weak or imperfect, those remedies which are most calculated to produce or to promote a tonic or contractile action of the womb. With this intention, I have directed the early application of the infant to the breast; and, if the uterus fails to contract sufficiently, an occasional dose of the biborate of soda, or of ergot of rye, or an enema containing spirits of turpentine with asafoetida. When, therefore, the disease commences thus locally, the cause is, owing to the circumstances just stated, more or less septic or contaminating, although the vascular reaction may be considerable, when the strength and habit of body of the patient are capable of developing it; and the local effect produced by this cause is generally of a diffusive kind. Admitting that the effect produced locally by this cause, or by any other calculated to occasion it, is of an inflammatory nature, the question still remains, Is the inflammation of a sthenic or asthenic nature, or to what amount may it be supposed possessed of either of these characters? That it is not purely sthenic inflammation of the parts, is shown by the state of the pulse and other constitutional symptoms, and especially by the rapid extension and consequences of the local mischief; and that it is either wholly asthenic, or largely possessed of this property, is proved by the constitutional disturbance, by the rapid diffusion of the local affection, and by the products of such affection. As it has been demonstrated by JOHN HUNTER, and confirmed by all subsequent observers, that asthenic or diffusive inflammations, and inflammations of circulating vessels, are not arrested or even mitigated by general vascular depletions, and hardly even by local depletions, but that they are aggravated in their most distinctive characters and consequences by this treatment, more especially by venesection, it is a matter of the utmost importance that some other than this most abused means should be resorted to. Cases, however, may occur where a nearer approach to sthenic inflammatory action, and a more robust and plethoric state of the patient may warrant a recourse to a moderate depletion; locally in preference, and early in the attack, especially when it is followed by the remedies about to be mentioned; but cautious observation and experience should direct this measure, too often recklessly prescribed by the insufficiently informed, or by the followers of worthless authorities, not a few of which have appeared in recent times.

265. Whether this form of the disease originate in the uterus or uterine vessels, or in the uterine appendages, or in the peritoneum, as shown, both here and in other places, to be probably the case in many instances; or whether it proceed from a constitutional infection received through the avenue of the respiratory organs, the local affection or affections being secondary or contingent, as contended for in respect of other instances (§ 245, *et seq.*), there is certainly no remedy so efficacious as a decided and judicious use of *spirit of turpentine*. This medicine was first employed for this disease by Dr. BRENAN, of Dublin; and although it has been “damned by faint praise” by subsequent writers, who either have not had recourse to it, or have employed it insufficiently or injudiciously, I can assert that it is the most efficacious remedy that can be employed in this

form of puerperal fever. I state this from a lengthened and diversified experience of this substance in disease; and yet in England I know not of any other physician than myself who has given it a satisfactory trial in puerperal fever, even up to the present day. I state this, in order that the remark may be disproved as regards the knowledge of others, and that I may be enabled to record the fact. The chief hinderances to the employment of this substance are, 1st. A mistaken view of the nature and consequences of its operation; 2d. Its nauseous or unpleasant effects; and, 3d. The opinion that it cannot be retained by the stomach when nausea and vomiting are complained of. As to the *first* of these, I can assert that it is, according to the mode of its exhibition, antiphlogistic in acute inflammations, and more efficacious in arresting the progress and consequences of asthenic or diffusive inflammations than any other substance; while it possesses the property of accommodating, by its tonic and astringent operation, the vascular and capillary system to the state and amount of its contents, of lowering the frequency of the pulse, and of restraining effusion from serous and mucous surfaces. That it is unpleasant, and that it is sometimes thrown off the stomach, I admit; but in many such cases it is beneficial nevertheless, its emetic action, independently of the impression produced by it on a vital organ, occasionally being of service, and even actually required. In those cases where the irritability of the stomach is even the greatest, it not only is the most easily retained, but is actually the most efficient remedy for the removal of the irritability, which, in the opinion of many, is the chief reason against a recourse to it. But the exhibition of it by the mouth is often not the only, and sometimes not the most beneficial way of prescribing it; for it may also be administered in enemata, or applied externally and occasionally, according to the nature of the case, even more efficaciously than in any other mode.

266. Although the spirit of turpentine may be more efficaciously employed in this form of puerperal fever than in the more sthenically inflammatory or in the malignant, still it is a valuable remedy, also, in both these extreme forms; in the inflammatory after sufficient vascular depletions, aided by other means, as described when treating of *inflammation of the Peritonæum* (§ 141, *et seq.*); and in the malignant, as will be shown hereafter. In this, the intermediate state of the malady, whether commencing locally or with a constitutional infection, this remedy is most beneficial when employed early, or before effusion into serous cavities, or softening or disorganization of the tissues has made much progress. In this, as well as in other forms of the malady, success depends upon a prompt recourse to treatment. If even a few hours elapse from the invasion, changes beyond the reach of remedies may have already supervened. If the symptoms and circumstances of the case, and especially the state of the pulse, indicate the propriety of a small or moderate venesection, or of local depletion, this should be immediately adopted; if the latter mode of depletion be preferred, a number of leeches, varying with the peculiarities of the case, may be applied near the seat of tenderness and pain;

and when they come away, flannels wrung out of hot water, and freely sprinkled with spirits of turpentine, should be applied over the abdomen, and covered by oiled silk or by a napkin; or the spongio-piline may be employed instead of these; and contemporaneously with the application of leeches, a full dose of calomel, camphor, and opium (calomel, gr. v.—viij.; camphor, gr. iii.—vj.; and opium, gr. ij.) ought to be given. A few hours after this medicine has been taken, about half an ounce of spirit of turpentine, and, if the bowels are not freely open, an equal quantity of castor oil should be taken on the surface of an aromatic water, or on spearmint water, or on milk, or in a cup of cold coffee. In most instances the intention is not so much to evacuate the bowels, for they are often sufficiently open, as it is to exhibit a remedy which is calculated, by its passage into the circulation, at least partially to resist the changes taking place in the blood and vascular system generally; and, at the same time, to procure the discharge, both from the bowels and from the uterus, of such morbid matters as would be inevitably most injurious if retained even for a short period. In prosecution of this intention, therefore, an enema containing spirits of turpentine should also be administered some hours afterward; the quantity of this substance, the medicines conjoined with it, and the time of having recourse to it, depending upon the peculiarities of the case. If the bowels are too frequently acted upon, castor oil should not be conjoined with it, either when taken by the mouth, or administered in a clyster; but olive oil may be substituted. Indeed, the latter may be very advantageously given with the spirit of turpentine in almost every state of the disease; for if the bowels should be too relaxed, the compound tincture of camphor or laudanum, or sirup of poppies, may be added; and emollients or demulcents may be made the vehicles for its administration, with olive oil, in enemata. The repetition of these medicines, of the turpentine more especially, the quantity of each, and their combinations, must necessarily depend upon the acumen and experience of the physician, upon the appropriate use of them, and upon the effects produced. But, with their internal employment—by the mouth or in clysters—a recourse to the turpentine embrocations or stupes should be persisted in as long as tenderness, pain, or distention in any part of the abdomen is complained of; and the above dose of turpentine should not be given by the mouth oftener than twice or thrice at the most.

267. If the urinary organs should become affected, either by the quantity of turpentine prescribed, or by its retention by the alimentary canal, the effects will soon disappear if demulcents are freely exhibited; and, if much depression be experienced, either from the operation of this medicine or the state and period of the malady, restoratives, such as quinine with camphor and capsicum, or wine taken in Seltzer water, or opium conjoined with aromatic stimulants, &c., may be administered, according to the state or urgency of the case.

268. *b. Metro-phlebitis* is one of the most frequent complications of this form of puerperal fever, although it is rarely recognised at an early stage. But, if recognised, should the

treatment be different from that now recommended for the arrest of this serious state of the malady? I believe that no other plan of cure will be found more beneficial for it than that now advised; that no other than powerfully restorative, tonic, and soothing means will be found beneficial in this form of phlebitis, or, indeed, in any other form. Dr. R. LEE, who has attached so much importance to metro-phlebitis as a pathological condition of puerperal fever, adds nothing to the treatment of this condition, and is even unaware of the means recommended, with great propriety, and often with great success, by JOHN HUNTER in cases of phlebitis. Dr. LEE gives us no farther information on this topic than to profess his want of confidence in the use of mercury for this state of the malady. HUNTER's treatment of phlebitis was powerfully tonic, stimulant, and restorative, and he directed it with the view—correct both in pathology and in therapeutics—of enabling the vessels of the diseased part to throw out lymph capable of coagulation, and of assisting the powers of life, by these or other means, to resist the progress and to retrieve the consequences of the disease. Of the use of oil of turpentine in this malady, Dr. R. LEE entertains a most unjust opinion. I question much the fact of his having given it a satisfactory trial. He distrusts the evidence furnished by Dr. BRENNAN's cases, is not convinced that the lives of those to whom it was administered were saved by it, and says that he has seen many recover without turpentine, in whom the symptoms were more unfavourable than in the cases described by Dr. BRENNAN; and that he has seen other patients in whom the disease appeared to be aggravated by its use. Now it would have been most desirable if Dr. LEE had favoured his readers with an exposition of the treatment which was so fortunate as to restore many cases in which the symptoms were more unfavourable than in those described by Dr. BRENNAN, seeing that in those turpentine had not been used; “sed de non apparentibus et non existentibus eadem est ratio.” Having myself since 1815 prescribed this substance in numerous diseases, malignant, febrile, and inflammatory, and having for many years—since about the above period—employed it in puerperal diseases, I have been induced to make inquiries respecting its use by other physicians; and yet, notwithstanding the notoriety of the practice, and its undoubted success if duly and appropriately prescribed, I have not heard of its having been employed by any other physician in this metropolis besides myself. This is somewhat singular, when the general fatality of the disease, and the highly favourable reports of the practice which have been made by Dr. BRENNAN, Dr. DOUGLAS, and myself, are considered. What are the obstetric practitioners, who appropriate the treatment of puerperal diseases, about? Should the obstetrician cease to be physician, in respect of liberality and candour of sentiment, and of a due appreciation and adoption of remedies recommended by others?

269. Let the opinion given by Dr. DOUGLAS, in an excellent memoir on puerperal fever, be the answer to this question as regards the remedy in question. He states that, in the epidemical and contagious puerperal fever, *zijj.* of the turpentine should be given, with an equal quan-

tity of sirup, and *3vj.* of water, three or four hours after the first dose of calomel; and that after an hour this should be followed by an ounce of castor oil, or some other purgative; or the turpentine and castor oil may be given together; and he restricts the internal use of turpentine to twice only. I have, however, given it even in a larger dose—in half an ounce—thrice in the same case, besides administering it in enemata and externally, with complete success; although I have found one or two doses more generally sufficient. “The external application of turpentine,” he adds, “without either its internal use or the aid of blood-letting, I have frequently experienced to be entirely efficacious in curing puerperal attacks; and although I have hitherto omitted to speak of turpentine for the cure of the other varieties of this disease, yet I should not feel as if I were doing justice to the community if I did not decidedly state that I consider it, when judiciously administered, more generally suitable, and more effectually remedial, than any other medicine yet proposed. I can safely aver, I have seen women recover, apparently by its influence, from an almost hopeless condition, certainly after every hope of recovery under ordinary treatment had been relinquished.” (*Dublin Hosp. Rep.*, vol. iii, p. 157.)

270. Now, without referring to my own experience and authority in the matter, and to the statements of that experience which have appeared in various quarters, I may remark that Dr. BRENNAN's publication was in 1814, and Dr. DOUGLAS's statement, now quoted, was made in 1822; and yet, unless in those cases for which I prescribed this remedy in Queen Charlotte's Lying-in Hospital, I am not acquainted with any sufficient trial which has been made of turpentine in any of the lying-in wards of this city. The eminent senior physician to the General Lying-in Hospital, writing in 1839, remarks as follows: “I have no experience of the use of this remedy (turpentine) introduced by Dr. BRENNAN in 1814, and praised by Dr. DOUGLAS of Dublin, and KINNEIR of Edinburgh, in puerperal fever.”

271. C. THE MALIGNANT OR PUTRO-ADYNAMIC FORM OF PUERPERAL FEVER (§ 198, *et seq.*), if not recognised at its commencement, and promptly treated, is always fatal. If even a few hours elapse from its seizure, the changes which have already taken place in the fluids, and even in the vital cohesion of the structures, are rarely arrested in their onward course by any treatment. The means of cure should therefore be early, promptly, and decidedly employed. When thus prescribed they are generally efficacious; at least they proved so in several outbreaks of this form of the malady in Queen Charlotte's Lying-in Hospital, especially when I had the advantage of the assistance of an intelligent resident pupil. In one of the most severe of these epidemics I had the aid of Dr. VOWELS, an intelligent and well-educated young physician, who was constant in his attendance, and who, immediately upon an attack, had recourse to the treatment about to be recommended, varying it according to my directions with the peculiarities of the case and the effects produced by the early part of it. On this occasion almost every case recovered. When I was first called upon to prescribe for

this disease in the hospital, the most malignant form prevailed, and every case that had occurred had terminated fatally. I first had recourse to DOULCER's plan of giving emetics, but it failed, probably owing to my being called at an advanced period of the disease. Having frequently employed the spirit of turpentine in the more malignant states of fever, and being aware of Dr. BRENNAN's recommendation of it for this malady, I next prescribed this substance, both by the mouth and in enema, trusting to it principally; but without obtaining from it all the advantages which I had expected. It should, however, be stated, that frequently I was not called to a case until it was far advanced. I was next induced, by my experience of the effects of large doses of calomel and opium in some acute diseases, to try the effects of these; but they still more signally failed. I afterward had recourse to both modes of treatment, and prescribed every four, five, or six hours a large dose of calomel and opium, and the spirit of turpentine with castor oil, the turpentine being employed both internally and externally. From this practice more success accrued than from either of the plans adopted singly. Yet as the success did not equal my wishes, and reflecting upon the phenomena, pathological conditions, and structural changes of the disease, I resolved upon trying the effects of camphor in large doses, in conjunction with calomel and opium, and sometimes with opium alone, or with quinine and capsicum, omitting the calomel, aided by the turpentine, in the manner about to be stated, and upon preceding these by an emetic when its use was indicated by the symptoms.

272. Immediately upon the accession of the disease, or as soon afterward as possible, from ten to twenty grains of calomel, from eight to sixteen grains of camphor, and from one to three grains of opium were administered in the form of bolus, with conserve of roses, the quantities of these medicines thus varying with the apparent severity of the case and the state of the pulse. In some instances, when vital depression was extreme, or the disease farther advanced, the camphor was conjoined with capsicum and opium, and occasionally either with ammonia or with sulphate of quinine, the calomel being omitted. The above were the extreme doses of the camphor, calomel, and opium; and when the largest quantities were given, five or six hours were allowed to elapse before they were repeated. If smaller doses were given, three or four hours only were sometimes allowed to pass. Soon after the second exhibition of these medicines, about half an ounce of spirit of turpentine, with or without castor oil, according to the state of the bowels, was taken as above directed; and a few hours afterward a larger quantity was administered in an enema, with castor oil or with asafoetida, and demulcents or emollients, as circumstances suggested. The intention was to make a strong impression on the constitution by means calculated to arrest the morbid action, and to counteract the changes taking place in the blood. Very soon after the development of the abdominal symptoms, especially the pain, distention, and tenderness, several folds of flannel, sufficient to cover the whole abdomen, were directed to be wrung as dry as possible out of hot

water, sprinkled very freely with turpentine, and applied as already described. This application was renewed at intervals, if the progress and symptoms of the case required a recourse to it.

273. In two or three hours after the treatment had advanced thus far—or after one or two of the boluses had been taken, and one dose of the turpentine and an enema administered—the symptoms had generally much abated, if these means had been early employed. In this case the doses of the camphor, calomel, and opium, or of the other combinations of which the bolus was composed, were diminished, and wine also given at the longest intervals above mentioned. The turpentine draught was seldom prescribed oftener than twice, and one only was taken in the twenty-four hours. It sometimes also contained an aromatic spice, as capsicum, &c. If the enema was soon thrown off, another was sometimes administered a few hours afterward, and the fomentation was renewed. If the malady resisted the first or second doses of these substances, the bolus was repeated a third, and sometimes a fourth time after the longer intervals, and in a few instances a third dose of the turpentine was ordered; or the enema containing it was repeated and conjoined with other medicines, according to the state of the bowels. If vital depression was extreme, the turpentine was given in small doses or withdrawn, and capsicum, or carbonate of ammonia, was taken in the bolus instead of the calomel; and a dose of decoction of cinchona, with chlorate of potash, carbonate of soda, and the compound tincture of cinchona or tincture of serpentaria was ordered in the intervals. If the lochia were very offensive, injections containing the solution of chlorinated soda were employed; and the same solution, or a solution of chloride of lime, was used in the wards.

274. If the symptoms evinced marked biliary disturbance or congestion, and the other indications for the exhibition of an *emetic* were present (§ 278), fifteen grains of ipecacuanha were given immediately and previously to the first dose of calomel, camphor, and opium; and the free operation of the emetic was promoted by the repetition of the same dose in an hour, and by the infusion of chamomile flowers. The emetic generally procured the early evacuation of much altered bile, both by the stomach and by the bowels, and also caused a copious sweat, which the camphor and opium farther promoted, and the terebinthinate embrocations on the abdomen tended to encourage and to perpetuate. But of the use of emetics in these cases I shall take farther notice in the sequel (§ 278).

275. When the above treatment was employed early, or before either effusion into the peritoneal cavity or other structural change had supervened or made any considerable progress, it was generally successful both in preventing or arresting these changes, and in resisting farther alterations of the blood, as well as in removing such as may have already taken place, by increasing the depurating actions of the several excreting organs. The successful employment of the above means required the constant attendance of an intelligent assistant as well as the frequent visits of the physician. During the prevalence of the disease I visited the cases three or four times in the day, direct-

ing the repetition, succession, or modification of the above remedies, according to their effects or to circumstances. If beneficial results did not follow after a very few doses—after the repetitions of the medicines as now stated—or if they did not appear in from twenty-four to forty-eight hours after their first exhibition, the patient rarely recovered. In some extremely malignant cases, for which I did not consider the calomel to be indicated, as well as in others which I did not see sufficiently early, I prescribed emphor in large doses, with capsicum and moderate doses of opium, and sometimes also in conjunction with the sulphate of quinia, which, at the time of the occurrence of these worst cases, was coming into frequent use. In some of these very hopeless cases these means, aided by an occasional dose of turpentine, given either by the mouth or in an enema, and by the external application of this substance, proved almost unexpectedly successful. In others, however, a temporary check only appeared to be given to the disease, the duration of this improvement being seldom longer than a few hours; these cases suggesting the conviction that the changes observed after death had advanced too far to be removed by the agents employed in medical practice. Of the other means which were occasionally tried in this and the preceding varieties of the disease, mention will be made in the sequel.

276. *B. REMARKS ON SEVERAL MEANS OF CURE, &c.*—In many of the works which have appeared on puerperal fevers some particular remedy or method of cure has been recommended, empirically rather than conformably with rational views of the pathology of these diseases; and in most of these the treatment, which seemed, in the eyes of those recommending it, successful to an extent which satisfied their expectations, was lauded as altogether applicable to all appearances of these maladies which may hereafter occur. But while each held forth his own method as most worthy of adoption, other methods, which had been equally praised by equally sanguine predecessors, met with little approbation, if, indeed, they escaped a complete condemnation. It would neither be gracious nor profitable to trace the various differences of opinion as to the treatment of these diseases to their sources; for some of them may be referred to those imperfections of our nature, which medical practice is calculated to develop and to foster when not directed and elevated, in its ethical relations, by the higher and more generous sentiments; while others may appertain to the very different forms of these maladies in different occasions, circumstances, and epidemic constitutions. With no marked disposition to be skeptical on the one hand, or to be credulous on the other; not disposed, with saintly faith, to place much confidence in that which I cannot explain, or to believe in what appears impossible, still I cannot attempt to set limits to the operations of nature, or to the influence of mind and its numerous manifestations on the vital actions. What may appear now as at least improbable may hereafter be found to be entirely in agreement with some principle hitherto concealed from our superficial knowledge. The unknown may seem difficult, complex, unfathomable, and even unattainable, but, once known, it may be easy,

simple, obvious, and within the reach of every intellect. The malady which is found to-day fatal, malignant, and pestilential may be proved to-morrow to be possessed of these properties only in virtue of our ignorance, and of our endeavours to encounter a formidable calamity by complex and ill-understood means; simpler agents, promptly and efficiently applied, accomplishing the ends, with a direct and beautiful simplicity, which were attempted, under the delusions of "false science," by multiplied and inappropriate measures and jarring influences.
